INDEX.

Abdominal; cavity, hemorrhage into, 340; wounds, treatment of, 441; fistula, operation for, 523; pregnancy, 594.
Abortion, 314.
Abscess; intra-peritoneal, 170; of female urethra, 185; mammary, to prevent, 312; tubo-ovarian, 360; mammary, 424; hepatic, treatment of, 537; idiopathic, 614; of ovary, 616.
Abscesses, 200; syphilis, 200; chronic, treatment of, 435.
Absorption of red blood corpuscles, 663.
Abstraction of blood in apoplexy, 72.
Acetate of copper in pulmonary diseases, 186.
Acid; carbolic, injections, 155; new use for, 191; poisoning, 399; whooping-cough, 409; distinguishing solutions of, 666; nitric, poisoning by, 118; death from, 506; sozolic, 378; benzoic and salicylic, use of, 527; chromic *vs.* galvano-cautery, 730; salicylic, eruptions from, 731; in erysipelas, 756.
Acne, treatment of, 569.
Acquired syphilis, 155.
Aconitine an anæsthetic, 535.
Acromegalia, 472.
Action of tin on animal organism, 566.
Acute; dysenteries, treatment of, 112; carbolismus, 119; pneumonia, treatment of, 269; peritonitis, ovariotomy during, 300; eruptive disease, 309, 419; menstrual pains, 315; rheumatism, nitrate of potassa in, 371; inebriety, 391; hemorrhage, injections in, 408; inversion of uterus, 526; gonorrhœa, treatment of, 535; multiple gangrene of skin, 662; pneumonia in utero, 729.
Adenitis, treatment of, 411.
Adirondacks a health resort, 129.
Addison's disease, 48, 441, 504.
Administration of drugs, 210.
Adolescence; disorders of, 521; tonsillitis in, 595.
Adulterant of castor oil, 319.
Affections, conjunctival, 737.
African king, doctoring an, 607.
Age of trees, 159.
Ague cake, quinine in, 468.
Albumen; in urine, tests for, 121; Bright's disease without, 336; nitric acid in testing, 497.
Albuminuria, Bright's disease, 185.
Alcoholic; paraplegia, diagnosis of, 378; red nose, 734.
Alcohol; origin of, 383; monopoly in Switzerland, 765.
Alexander's operation, 632.
Alkaloids in hot-house plants, absence of, 671.
Allyl, tribromide of, 569.
Alopecia; of scalp, 25; prescription for, 411.
Alternatives to craniotomy, 555.
Ambiguous charity, 542.
Amblyopia, case of tobacco, 713.
Amputation, 200; above elbow, 26; prolapse of rectum by, 305; of right thigh, 337; supra-vaginal, 332; dressings after, 641; of leg, 641; of hand, 642; of foot, 642; for senile gangrene, 695.
Amyl nitrite; antidote to cocaine, 251; use of, 298.
Anæmia; treatment of, 346; pernicious, 377; post-menstrual, conception at, 435.
Anæsthesia; Esmarch's bandage in, 375; by suggestion, 408.
Anæsthetic; local, cocaine as, 248, 745; warm ether as, 280; during sleep, 376; aconitine an, 535; effect of ointments, 720.
Anæsthetics; new local, 251; in child-birth, 405; on living tissue, 667.
Analysis of food, 127.
Anatomical Institute in Vienna, 669.
Anatomy, intubation, and pathological, 805.
Anderjou, 186.
Aneurism; cirsoid, treatment of, 24; thoracic, treatment of, 90; of subclavian artery, 90; ligature of right carotid for, 179; of innominate artery, 418; popliteal, cured by pressure, 634.
Angina pectoris, cocaine in, 438; of artery of Sylvian fissure, 808.
Animal; lymph, vaccination with, 309; organism, action of tin on, 566.
Ankylosis, recovery without, 644.
Anodyne for vesical irritation, 407, 569.
Anteversion, extraordinary, 345.
Anus, imperforate, 148.
Anthelmintic, naphthalin an, 538.
Anthracis bacillus, effect of light on, 31.
Antidote; to cocaine, 251; poisoning, 23; to strychnine, 505; to phosphorus, 506.

Antifebrin, 601.
Antipyretic, a new, 763.
Antipyrine, 409; action of, 442; in headache, 464; in infantile therapeutics, 539; depressing effect of, 562; during pregnancy, 603; in pyrexia, 700.
Antisepsis; intestinal, 115; value of, 164, 195, 225, in military surgery, 286; illustrated, 641; legal aspect of, 763.
Antiseptic; corrosive sublimate an, 48; paper; 191; methods, value of, 243; vinegar an, 342; paper, 347; treatment, 607; dressing, 762.
Appendix vermiformis, rupture of. 631.
Aphasia, 717; puerperal, 56.
Aphonia, hysterical, 110.
Aphthæ of vulva, treatment of, 314.
Apone, new pain-killer, 314.
Apoplexy; abstraction of blood in, 72; hysterical, 556.
Apormorphia in singultus, 635.
Applications, local use of, 210.
Arabic medical paper, 446.
Argyria, new manifestation, 699.
Arm, echinoccus in, 249.
Arsenic in skin diseases, 159.
Arsenical wall-papers utilized, 94.
Arteries; ligature of, 179, 665; vertebral, ligation of, 247.
Artery; subclavian, aneurism of, 90; brachial, ligature of, 280; aneurism of, 418; cerebral, embolism of, 718; femoral, ligation of, 794; of Sylvian fissure, aneurism of, 808.
Artificial; coloring matters in wine, 30; heel by grafting, 116; tape-worms, 512; feeding vs. wet-nursing, 782.
Ascarides, poisons on, 22.
Ascites; recovery from, 303; chylous, 44; diagnosis of, 631, 793.
Asepsis not antisepsis, 73, 105.
Aseptic surgery, 695.
Asphyxia; of extremities, 144, 271; of new-born, 283; death by, 543.
Asphalgesia in hysterical patients, 728.
Aspiration of bladder, 266.
Asthenic type of fever, 654.
Asthma; salicylate of cocaine in, 184; bronchial, theory of, 215.
Astigmatism in twins, 779.
Astley Cooper prize, 92
Astragalus, dislocation of, 339.
Ataxic; fevers, solvent for sordes in, 536; paraplegia, 600.
Ataxy, locomotor, symptoms of, 17.
Atropia in plus tension, 397.
Atrophy; of left arm, 91; muscular, 474, 615.
Atropine and morphine, 759.
Austin Flint, a memoir of, 605.
Avulsion of scrotum, 281.

Bacilli, tubercle, in Addison's disease, 48.
Bacillus; anthracis, 31; of typhoid fever, 251; comma, heat to, 411; comma, polymorphism, 761.
Bacteria in sea air, 350.
Bacteriologist, the first, 126.
Bacterio-therapy in pulmonary tuberculosis, 467.
Balsam of copaiba in gonorrhœal ophthalmia, 627.
Bandage, obstetric, 763.
Basedow's disease, operation for, 248.
Baths; electric, in eye diseases, 183; warm, in scarlatina, 282; danger from public, 413; hot, danger of syncope in, 627.
Bathing, gonorrhœa from, 345.
Bay rum in West Indies, 159.
Beauty trade, 413.
Beautifying the skin, 337.
Belladonna poisoning, temperature in, 667.
Benzoic acid, use of, 527.
Bichloride of mercury; for consumption, 402; in uterine catarrh, 787.
Bile, that, 348.
Bigotry in the profession, 597.
Bile-duct, microbes in, 759.
Birth-places of vegetables, 286.
Birth, the blood at, 756.
Bismarck and his doctor, 124.
Bismuth, subnitrite, in fœtid feet, 407.
Bisulphide carbon in neuralgia, 506.
Bitemporal hemianopsia, 683.
Black tongue, 557.
Bladder; aspiration of, 266; rupture of, 600; exploration of, 602; catheter in male, 728.
Bleeding from under lip, 687.
Blindness and fecundity, 473.
Blood; changes in endarteritis, 312; catheter, 370; malarial, study of, 558; at birth, 756.
Blue discoloration, sign of pregnancy, 626.
Boric acid tooth powder, 311.
Botanical explorations in Costa Rica, 797.
Bowditch on homœopathy, 60.
Boy with cat's eyes, 381.
Brachial artery, ligature of, 280.
Brachioplegia after injury, 20; by rheumatism, simulation of, 304.
Brain; disease of, 17; of Gambetta, 316; bullet in, 344; in children, treatment, 367; gunshot wound of, 442; idiopathic abscess of, 614; lesions from injuries of head, 728; paths of fibres in, 789; of hysterical person, 790.
Breast; measurement of, 24; milk in consumption, 345; painful hypertrophy, 727.
Breathing cold air, 127.
Bright's disease; without albuminuria, 185; digitalis in, 217; exudative retinitis, 218; chloride of sodium in, 240; salt in, 247; without albumen, 336; detection of, 368; of kidneys, 385; causation of, 698; humorist on, 797.
Bromide; of potassium in sunstroke, 155; of potassium, tolerance of, 493; of ethyl with chloroform, 779; of potassium, rare lesions by, 787.
Bromides in hyperpyrexia, 344.
Bromine in diphtheria, 121.
Bronchial asthma, theory of, 215; hepatic fistula, 761.
Bronchocele, treatment of, 656.
Bruises, treatment of, 313.
Bubo, radical cure of hernia by, 279.
Bulbous eruption from salicylic acid, 731.
Buboes, treatment of, 371.
Buried in chains, 124.
Burns; treatment of, 87; cocaine for, 306.
Bursting cyst of ovary, 620.

Cachexia strumpriva, 368.
Cæcum; hernia of, 700; epitheliomatous tumor of, 810.
Cæsarian operation, 23, 105.

Caffein; a diuretic, 410, 502; in heart disease, 760.
Calabar bean in epilepsy, 313.
Calcification of coronary arteries, 806.
Calcium, sulphide of, 347.
Calculus; in women, 185; urinary fistula maintained by, 346; removal of, 369; large vesical, 447.
Calomel in syphilis, 439; a diuretic, 502.
Cancer; uterine, treatment of, 25; uterine, diagnosis, 104; coincidence in history of, 123, 397; rectal operation for, 281; and longevity, 342; of mamma, 375; powder, 378; renal diagnosis of, 430; of œsophagus, 433; of spleen, 630; rapid course of 792.
Canquoin's paste, 538.
Capital punishment, commission on mode of, 796.
Capsules, supra-renal, 471.
Carbolic acid; injections, 155; use of, 191; poisoning, 399; whooping-cough, 409, 667; distinguishing solutions of, 666; in erysipelas, 756; injections in hydrocele, 794.
Carbolismus, acute, 119.
Carbolized iodine in phthisical lung, 805.
Carbon bisulphide in neuralgia, 506.
Carbuncle; treatment of, 109, 282; carbolic acid in, 155; permangate of potash in, 376.
Carcinoma cervicis uteri, 46.
Cardiac; changes in typhoid fever, 25; mitral murmurs, 55; neurosis in uterine disease, 307; disease, chorea with, 460; degeneration, 481; orifice, schirrhus of, 678.
Carotid, ligature of, 179.
Cascara cordial, 517.
Case; of delirium tremens, 45; recurrent proliferous cyst, 49; deformities of chest, 83; gunshot wound, 83; syphilis, 122; removal of fallopian tubes, 146; imperforate anus, 148; osteosarcoma, 175; malarial fever, 180; cholecystotomy, 182; disease, 187, 218; primary labio-pharyngeal paralysis, 203; ununited fracture, 247; asphyxia of extremities, 271; poisoning by chloroform, 273; intussusception, 274; ovariotomy, 332, 420; tuberculosis of skin, 407; amputation of thigh, 337; lymphoid growth, 426; extirpation of scapula, 435; cholecystotomy, 436; hydatid disease of liver, 498; acute inversion of uterus, 526; spurious hermaphroditism, 528; dysidrosis of face, 528; gunshot, 530; strangulated hernia, 557, 562; congenital absence, 584; chronic cirrhotic kidney, 590; spina bifida, 592; abdominal pregnancy, 594; labor, obstructed, 600; nerve stretching, 602; hemorrhage after coitus, 602; fibro-sarcomatous tumor, 618; voluntary starvation, 632; fracture of skull, 659; post-partum hemorrhage, 662; gangrene of legs, 663; multiple hemorrhage, 664; vulvo-rectal fistula, 664; scarlet fever, 664; of pseudo epilepsy, 742; of walking typhoid fever, 744; double vagina and uterus, 665; peculiar, 668; bitemporal hemianopsia, 683; subacute spinal paralysis, 686; of pregnancy, 750; of tubercular inoculation, 760; removal of scapula, 691; lupus treated with iodoform, 696; quinine rash, 699; paralysis agitans, 700; of lupous stricture, 763; paresis of forearms, 717; of tobacco amblyopia, 713; of pleurisy, 778; of iodide potassium eruption, 792; of renal surgery, 810.
Castor; oil, new adulterant, 319; bean, poisoning with, 377.
Castration; in mental and nervous diseases, 622; in myo-fibromata of uterus, 633.
Catarrh; pharyngeal, 469, 538; treatment of, 488; autumnal, morphia for, 496; gastric, condurango in, 634; uterine, bichloride of mercury in, 787.
Catarrhal; headache, 314; icterus, treatment of, 534.
Cataract operations, treatment of, 317.
Catheter; fever, 89; in paraplegia, 153; blood, 370; in male bladder, 728.
Caught in his own trap, 157.
Cause; of pruritus and leucorrhœa, 27; of gastric ulcer, 727.
Cautery; intra-uterine galvano-, 440; thermo-, in herpes, 553.
Cellulitis; atrophy of arm from, 91; ligature of brachial artery for, 280.
Centenarians, pair of, 319.
Cerebellum, removal of tumor from, 762.
Cerebral; and spinal trouble, 58; hemorrhage, 299; infantile paralysis, 525; tumor, excision of, 559; artery, embolism of, 718.
Cervix uteri; dilatation of, 56; lacerations of, 264; epithelioma of, 326.
Cervical; pachy-meningitis, 491; canal, dilatation of, 645.
Chancre; of ear, 278, 311; syphilitic, of eyebrow, 312; of gum, 462.
Cantharides in bites of rabid animals, 730.
Charity Hospital of New York, 615.
Charms and superstitions, 540, 732.
Chemical science in Japan, 158.
Chemist family, 351.
Chest, congenital deformity of, 83.
Chevreul's household, 379.
Child; -birth, anæsthetics in, 405; a two-pound, 415; -bearing, late, 448.
Childhood, diabetes in, 763.
Children; treatment of diarrhœa in, 183; lithotomy in, 242; rheumatism in, 277; temperature in, 409; incontinence of urine in, 427; male, conception of, 435; treatment of diarrhœa in, 666; hysteria in, 693; thread-worms in, 697.
Chilliness, recurring attacks of, 143.
Chinaman, in tea making, 92.
Chinese medical missions, 59.
Chloral hydrate; in tetanus, 48; band, 127; tolerance of, 493.
Chlorate of potassium in miscarriages, 308.
Chloride; of sodium in Bright's disease, 240; therapeutics of, 273; in subinvolution of uterus, 624.
Chlorodyne drinking, 373.
Chloroform; poisoning by, 273; *vs.* parturition, 611, 770; bromide of ethyl with, 779.
Chlorophyll; in plants, 158; under water, 383.
Chlorosis, treatment of, 346.
Chlous ascites, 501.
Cholecystotomy, case of, 182, 436.
Cholera; prospects in Paris, 191; treatment of, 250; in Hungary, 478; hospital in Rome, 508; report on, 726.
Chorea; syphilitic, 432; fatal case of, 460; treatment of, 577; and rheumatism, relations of, 710, 713; hysoscyamine in, 811; cimicifuga in, 769.

Chromic acid *vs.* galvano-cautery, 730.
Chronic; ulcers, treatmeut of, 50; insane, recovery of, 280; metritis, treatment of, 340; cirrhotic kidney, 590.
Chylous ascites, 440.
Cicatricial deformity of foot, 644.
Cimicifuga racemosa in chorea, 577; in chorea, 769; in rheumatism 769; in pregnancy 769.
Circulation, feeble, 272.
Circumcision; under cocaine, disease following, 462; substitute for, 700.
Cirrrhosis of liver, 120, 410, 459, 539.
Cistern, clean, how to, 62.
Cleanliness, importance of, 544.
Climate; and mode of life, 209; of Colorado, 547.
Climacteric diabetes in women, 88.
Cocaine; poisoning, 23 779; habit, 31, 672, 683; in labor, 57; in vomiting in pregnancy, 57, 568; in facial neuralgia, 89; a diuretic, 91; remedy for rose-cold, 123; spray in epistaxis, 156; in asthma, 184; in mercurial stomatitis, 217; aided by electricity an anæsthetic, 248; antidote to, 251; for burns and blisters, 306; solutions unalterable, 346; craze, 432; in angina pectoris, 438; circumcision under, 462; in hemorrhoids, 494; in tooth extraction, 506; poisoning, nitrite of amyl in, 634; a victim of, 636; in gonorrhœal ophthalmia, 700, 745; note on, 731.
Cocainomania, 474.
Cod-liver oil to infants, 635.
Coffee; stain patches, 238; pruritus ani from use of, 792.
Coincidence, an unusual, 703.
Coition, abnormal œdema of penis from, 400.
Coitus; hemorrhage after, 602; vesico-rectal fistula from, 664.
Cold; air, breathing of, 127; the strangers, 465.
Colombine, 567.
Colon and stomach, 121.
Colorado Springs, observations at, 547.
Collodion; in small-pox, fatal effect of, 313; death from, 543.
Colored eclectics, 679.
Comma bacillus; heat to, 411; polymorphism, 761.
Complexion, the Teutonic, 560.
Conception of male children, 435.
Concussion, 409.
Condurango; in gastric diseases, 507; catarrh, 634.
Confinement, Turkish, 59.
Congenital deformity of chest, 83; of forearms, 281; malformation of ear, 249; absence of coordination, 584, 723; defect of tonsils, 807.
Congestion of brain, 367.
Conjunctiva, pemphigus of, 343.
Conjunctival affections, 737.
Conservative ovariotomy, 633.
Constipation, 122; and epilepsy, 83.
Consultants and general practitioners, 311.

Hoang-nan, treatment of rabies with, 307.
Homœopathy; Bowditch on, 60; in defence of, 287; the progress of, 606.
Hopeine, what is? 511.
Hot baths; effects of, 50; in puerperal peritonitis, 342.
Humerus; fracture of, 204; ununited fracture of, 247; injury to epiphysis of, 239.
Hospital of London, day in, 784; New York skin and cancer hospital, 795.
Hospitals of Paris, 525; service of France, 702; the Vienna, 734.
Hyaline casts, detection of, 366.
Hybrid, 345.
Hydatid; cysts of lung, 283; disease of liver, 498.
Hydrate, chloral, band, 127.
Hydrocele, operation for, 308; radical cure of, 794.
Hydrogen peroxide; in disease of eye, 398; in epilepsy, 411.
Hydrophobia, 761; Chinese remedy for, 123; and imagination, 339; prescription for, 349; in the ass, 350; recovery from, 475; spiræa filipendula in, 567.
Hygenic; enterprise, 149; therapeutics, 161, 192.
Hymen, imperforate, 17.
Hyoscyamine; uses of, 585; in chorea, 811.
Hyperæsthetic rhinitis, 68.
Hyperidrosis of feet, 283.
Hyperpyrexia, bromides in, 344.
Hypertrophy of breast, 727.
Hypermetropia, case of, 742.
Hypnosis, delivery during, 119.
Hypnotics, concerning some, 623.
Hypnotism, mental diseases cured by, 505.
Hypodermic; syringe, how to keep, 31; solution of quinine, 57, 251, 569; syringe and nurses, 287; injections of calomel, 439.
Hypodermically, morphia, 443.
Hysterectomy; for removal of tumor, 137; and nephrectomy, 250.
Hysterorrhaphy, 749.
Hysteria; treatment of, 91; in army, 599; in children, 693; shedding nails in, 698.
Hysterical; monoplegia in male, 85; aphonia, 110; women, tympanites in, 472; apoplexy, 556; hemiplegia, 602; patients, hæmatemesis in, 699; patients, asphalgesia in, 728; person, brain of, 790; borborygmus, 793.

Ice; in sick room, 317; bag, 346; enemata, 664.
Ichthyol; in rheumatism, 475; uses of, 507.
Icterus; neonatorum, 202; emotional, 466; catarrhal, treatment of, 534.
Idiopathic abscess, 614.
Idrosis, simplex, 135.
Ileus, treatment of, 55.
Illegal practioners, 213.
Imagination and hydrophobia, 339.
Imperfectly and ill shapen jaws, 631.
Imperforate; hymen, 17; anus, case of, 148.
Imperial University of Japan, 30.
Imprisoned for malpractice, 286.
Importation of rags, 287.
Inaugural address, 203.
Incisor tooth in orbit, 283.
Incombustible, render wood, 158.
Incontinence of urine in children, 427.
Indestructible paste, 159.
India-rubber catheter in male bladder, 728.
Induction of premature labor, 468, 503, 603.
Indurated chancre of ear, 311.
Inebriety, acute, 391.
Inebriates, 56.
Inequality in length of tibiæ, 24.
Inertia uteri, cause of, 347.
Infant; multiple hemorrhage in, 664; mortality, 686.
Infantile; malignant jaundice, 434; cerebral paralysis, 525; therapeutics, antipyrin in, 539; erysipelas, 677; diarrhœa, prescription for, 794.
Infanticide in China, 381.
Infancy, phimosis in, 599.

Infants; new-born, asphyxia of, 283; sore mouth of, 569; cod-liver oil to, 635; food of, 781.
Infection, surgical, pathology of, 164, 195, 225; venereal, a crime, 797.
Infections or traumatic pneumonia, 661.
Infectiousness of chronic gonorrhœa, 697.
Inflammation; of veins, ointment for, 378; renal, 507.
Influence; of water on nutrition, 29; of companions in education, 670; of light on ferments, 765.
Ingluvin, 531.
Ingrowing; toe-nail, 282; toe-nail, treatment of, 730.
Inheritance, therapeutical, 591.
Inherited gout, 272.
Injection; intra-peritoneal, in hemorrhage, 492; of cocaine in hemorrhoids, 494; uterine, death following, 633; a phthisical lung, 805.
Injections; in phthisis, 56; mercurial, in syphilis, 122; carbolic acid, 155; in acute hemorrhage, 408; of iodoform in abscesses, 435; hypodermic, of calomel, 439; of quinine in ague cake, 468, 631; rectal, of medical gases, 601; of apomorphia in singultus, 635; intra-pulmonary, 793; carbolic acid in hydrocele, 794.
Injury; to head, 207; to lower epiphysis, 239; of finger, 535; to vesiculæ seminales, 760; by finger-ring, 795.
Injuries; scarlet fever from, 408; of head, optic neuritis in, 722; to head, brain lesions from, 728; malformation of, 729.
Inoculation; for yellow fever, 221; of intermittent fever, 402; tubercular, 760, 793.
Insane; surgical affections in, 23; chronic, recovery of, 280; delusions, 374.
Insanity; lectures on, 33, 65; of somatic origin, 260; malarial, 347; reflex, 347.
Insect powder, ricinus communis an, 511.
Insects, lead-eating, 510.
Insufflation, nasal, in whooping-cough, 270.
Intermittent fever; inoculation of, 402; piperine in, 461; phosphorus in, 537; quinine in, 568.
Internal hemorrhoids, 283.
International; Medical Congress, 27, 190, 254, 276, 570, 638; Exhibition at Barcelona, 734; Health Congress, 766; Medical Congress of Climatology, 287.
Intestinal canal; what part do contents become feculent? 88, 257; antisepsis, 115; perforations, 281, 744; obstruction, 443, 536; tract, opium upon, 603; lesions, due to mercuric chloride, 658.
Intestine; lymphadenoma of, 155; sloughing of, 274; collapsed in laparotomy, 443.
Intracranial hemorrhage, 41.
Intraperitoneal; abscess, 170; injection in hemorrhage, 492.
Intra-pulmonary injections, 793.
Intubation; of larynx, 362, 393, 524, 586, 595, 779; and pathological anatomy, 805.
Intussusception, case of, 274.
Invalid diet, fish an, 634.
Inversion of uterus, 526.
Investigations; careful, 117; laboratory, 222.
Involuntary muscular movements, 15.
Iodide of potassium, poisoning by, 756; eruption, 792.
Iodine in diphtheria, 121.
Iodinism, 116.
Iodism cured by sulphanilic acid, 311.
Iodoform in lacerated cervix, 114; in indolent ulcers, 122; injections of, 435; lupus treated with, 696; vaseline in small-pox, 762.
Iowa State Board of Medical Examiners, 255.
Iritis, syphilitic, treatment of, 250.
Iron; salicylate, in diarrhœa, 378; in diabetic patients, 471; danger of large doses, 538; sulphate, in diarrhœa, 667.
Irregular medical schools, 478.
Irrigation pump for stomach, 210.
Irritable brain, treatment of, 367.
Irritation; genital, 26; renal, 216; vesical, anodyne for, 569.

Jamaica dog-wood, 154.
Jaundice; malignant, infantile, 434; nature of, 442; hemorrhage in infant followed by, 664.
Jaws imperfectly shapen, 631.
Joints, neuropathic affections of, 593.
Johns Hopkins' endowment, 638.

Keratitis, suppurative, 674.
Kidney; statistical operations on, 281; chronic, cirrhotic, 590.
Kidneys, Bright's disease of 385.
Knee-joint; gunshot wound of, 152; disarticulation of, 337; laceration of, 644.
Kœnig's flexion contracture, 630.

Labium, varix of, 561.
Labor; cocaine in, 57; cases of, 108; an impediment of, 344; retained placenta during, 369; by suppression of urine, 378; ergot in, 464; premature induction of, 468, 503, 603; obstructed, 600; method of inducing, 632; twin complicated, 722.
Laboratory investigation, electric light in, 222; of Pasteur, 525.
Lacerated; cervix, treatment of, 114; perineum, operation for, 785.
Laceration of knee, 644.
Lacerations of cervix uteri, 264.
Lachrymal glands, enlargement of, 793.
Lady doctors in fifteenth century, 93.
Landry's paralysis, 296.
Lanolin; 443; an old remedy, 24, 26; basis for ointments, 186, 730; in cutaneous diseases, 410; combinations of, 538; midwifery practice, 731.
Laparotomy; ileus cured by, 55; not paraphernalia in, 73, 105; collapsed intestine in, 443.
Laryngeal diphtheria, 805.
Laryngitis; œdematous, 411; ulcus syphilitica, 673.
Larynx; intubation of, 362, 393, 524, 586, 595, 779; papilloma of, 647, 761; syphilitic ulceration of, 673.
Lawson Tait, pen picture of, 414.
Lead poisoning; from eating, 155; pencils, 224; eating insects, 510.
Leech, serious oral bleeding after, 312.
Leg, amputation of, 641.
Legs, gangrene of both, 663.
Lemonade tablets, 223
Length of step, 735.

Leper hospital at Bergen, 92.
Lepers, life among, 317.
Leprosy and syphilis, 374.
Leucorrhœa; cause of, 27; red ants and, 346.
Lice, mercurial inunctions for, 396.
Lichen, emotional, 466.
Licensing boards in Canada, 415.
Life; length of, 70; cause of failure in, 284; among lepers, 317; insurance, 355.
Ligation; of vertebral arteries, 247; of femoral artery, 794.
Ligature; of right carotid, 179; of brachial artery, 280; of arteries, 665.
Light on bacillus anthracis, 31.
Lightning, the work of, 798.
Linseed-oil in pruritns ani, 282.
Liquor statistics, 414.
Liquorice powder, 567.
Lister's latest antiseptic dressing, 762.
Lithotomy in children, 242.
Liver; cirrhosis of, 120, 410, 459, 539; disease of, 303; hydatid disease of, 498.
Living tissue, anæsthetics on, 667.
Locomotor ataxy, symptoms of, 17.
Longevity and cancer, 342.
Lotion for rhus poisoning, 603.
Love powders, 383.
Lunacy commission, 448.
Lung; nephrectomy of, 50; hydatid cyst of, 283; or liver, 699.
Lupous stricture, case of, 763.
Lymphadenoma of intestine, 155.
Lymphatic obstruction, enlargement from, 762.
Lymphoid growth, case of, 426.

Malarial; hæmaturia, 1, 35, 102, 156, 410; fever, 180; insanity, 347; disease, oil of eucalyptus in, 495; blood, study of, 558.
Male; mollities ossium in, 110; nurses are best, 223.
Malformation; of thorax, 22; congenital, of ear, 249; of intestine, 729.
Malignant infantile jaundice, 434.
Malingerer, a clever, 253.
Malpractice, imprisoned for, 286.
Mamma, cancer of, 375.
Mammary; neuralgia, 187, 603; abscess, to prevent, 312; abscess, 424.
Man; is often sterile, 151; the protean, 605.
Manaca in muscular rheumatism, 659.
Mange in horses, 639.
Manganese in menstrual disorders, 345.
Manure, baling stable, 777.
Mary thistle, 495.
Massage; treatment of diabetes by, 315; effect of, 470; in fractures, 539; morals of, 542, 701.
Masseuses in Vienna, 30.
Maternal nursing, 686.
Maxilla, inferior, sarcoma of, 175.

Palpebrarum pediculosis, 182.
Palsy, night, 81.
Papilloma; of trachea, removed, 442; of larynx, 647, 761.
Paracentesis pericardii, 492.
Paraffin lamps, how to extinguish, 511.
Paraldehyde, 378; an antidote to strychnine, 505.
Paralysis; primary labio-glosso-pharyngeal, 203; of sensation in forearm, 204; Laudry's, 296; depending upon idea, 457; infantile cerebral, 525; after tonsillitis, 537; agitans without shaking, 537; subacute spinal, 686; agitans, case of, 700.
Paraplegia; catheter in, 153; myelitis or reflex, 154; alcoholic diagnosis of, 378; ataxic, 600.
Parenchymatous injections of quinine, 631.
Parasiticism in dermatology, doctrine of, 205.
Paresis; of respiratory muscles, 408; of forearms, 717.
Parisian fish, 128.
Paroxysms of whooping-cough. 91, 298.
Parsnip, poisonous properties of, 534.
Parturition; ergot in, 377; *vs.* chloroform, 611, 770.
Pasteur; M., 157, 671; institute, 21, 703; opposition to, 286; life of, 486.
Patella, ununited fracture of, 249.
Patent medicines in America, 379.
Pathogenic; cause, 54; microbes, passage of, 120.
Pathology; of surgical infection, 164, 195, 225; of hay fever, 215; evolution in, 350.
Patient; a troublesome, 62; and doctor, 575; a very perverse, 798.
Pediculosis, palpebrarum, 182.
Pelvic, hæmatocele, 466, 696.
Pemphigus of conjunctiva, 343.
Penis; œdema of, 400; retraction of, 400; gangrene of, 431.
Penitentiary, an intermediate, 680.
Pepsin, pharyngeal catarrh and, 469, 538; possible danger from, 794.
Peptonization, effects of drugs on, 47.
Percussion cap in eye, 242.
Pericardii paracentesis, 492.
Perineum; rupture, 250; a supporting structure, 262; ruptured, operation for, 264; exploration of bladder through, 602; lacerated, operation for, 785.
Peritonitis, ovariotomy during, 300; due to the perforation 778.
Perityphlitis, treatment of, 483.
Permanent closure of orbital cavity, 279.
Permanganate of potash in carbuncle, 376.
Peroxide of hydrogen; in diseases of eye, 398; in epilepsy, 411.
Personal journalism, 53, 128.
Perspiration, disorders of, 135.
Pertussis, oxymel of squills in, 539.
Pharyngeal; paralysis, 203; catarrh and pepsin, 469, 538.
Philanthropy of Dr. Wakeley, 444.
Phimosis; with symptoms, 497, 559; in infancy, 599.
Phlebotomy; in acute pneumonia, 269; in puerperal eclampsia, 313.
Phosphorus; turpentine, an antidote to, 506; in intermittent fever, 537.
Photography, medical, 358.
Photographing; the uterine cavity, 94; in dark, 351.
Phthisis, 717; contagiousness of, 46; injections in, 56; fibroid, pulmonary, 246; oral disease and, 422; sweats of, 504; in Denmark, 561; prophylaxis of, 563; treatment of, 667; pulmonary and ovarian disease, 730.
Phthisical lung injected with carbolized iodine, 805.
Physician, a brutal, 480.
Physician; the American, 348; fee, 354, 604; dangers that beset, 406; as experts, 629.

Physiological; action of opium, 603; effect of piliganine, 666.
Physiology, electricity in, 30.
Phytolacca decandra in bronchocele, 656.
Piliganine, 506; physiological effect of, 666.
Pilocarpine; on nephritis, 50; in rheumatic, tetanus, 700.
Pine leaves causing hemorrhage, 697.
Piperine in intermittent fever, 461.
Pistol shot wound, 237.
Placenta; retained during labor, 369; fatty, causing hemorrhage, 564; new mode of extracting, 763.
Plants, chlorophyll in, 158.
Pleurisy, traumatic, 473; case of 778.
Pleuritic effusions, treatment of, 87.
Plus tension, atropia in, 397.
Pneumogastris, lesions of, 370.
Pneumonia; microbes of, 46; migrans, 84; digitalis in, 89; symptoms of, 90; coccus of Friedlander, 151; acute, treatment of, 269; rapid development of, 536; traumatic, infectious or, 661; acute, in utero, 729.
Poison ivy eruption, 348.
Poisons, action of ascarides on, 22.
Poisoned; with nitro-glycerine, 511; thousand sheep, 733.
Poisoning; cocaine, 23, 779; by nurse's cosmetic, 31; by ol. succini, 57; by nitric acid, 118; lead, 155; by chloroform, 273; from sorrel, 376; by sulphuric ether, 377; with castor oil bean, 377; opium, 396, 470; carbolic acid, 399; cases, 446; by squills, 537; lotion for, 603; belladonna, temperature in, 667; by ptomaines, 703; by iodide of potassium, 756; by misadventure, 765.
Poisonous; ginger beer, 148; properties of parsnip, 534; snakes, venom of, 691.
Polymorphism of comma-bacillus, 761.
Pomegranate bark, value of, 423.
Pons, gumma in, 471.
Popliteal; aneurism cured by pressure, 634; space, gunshot wound of, 643.
Population of Paris, 315; France and Italy 796.
Post-mortem; specimens, 517; of brain, 614.
Post partum hemorrhage, 662.
Potassa nitrate in acute rheumatism, 371.
Potassium; osmate of, 122; bromide in sunstroke, 155; chloride, 216, chlorate in miscarriages, 308; bromide, tolerance of, 493; iodide, poisoning by, 756; bromide, rare lesions by, 787.
Powdered beef-steaks as food, 351.
Powerful bottle, 441.
Pouch of penile urethra, 696.
Practice in India, 638.
Practicing to prevent, 679.
Practitioner (German), sad fate in South America, 285.
Practitioners, illegal, of medicine, 213.
Pregnancy; cocaine in vomiting in, 57, 568; extra-uterine, 77, 201; vomiting, 90, 411; influence upon cardiac disease, 139, 169; mammary abscess during, 424; effect of syphilis in, 465; excessive salivation during, 566; abdominal, 594; antipyrine during, 603; blue discoloration, sign of, 626; hæmoptysis complicating, 655; ovarian, 748; case of, 750; cimicifuga in 769; protracted, 786; rupture of uterus during, 790.
Pregnant women, mixture for, 378.
Prehistoric dentistry, 316.
Premature labor, indication of, 468, 503, 603.
Preputialis, herpes, 592.
Prescribing, counter, 8.
Prescription; a strange, 94; for hydrophobia, 349; book of eleventh century, 604; for infantile diarrhœa, 794.
Prevention of drowning, 603.
Prizes by French Society of Hygiene, 765.
Profanity, treatment of, 447.
Profession, bigotry in, 597.
Professional ethics, 679.
Professor Charcot "at home," 508.
Prognosis; mistakes in, 446; of croup, 754.
Progressive; facial hemiatrophy, 278; pernicious anæmia, 378; muscular atrophy, 474.
Prohibition "beverages," 479.
Prolapse; of umbilical cord, 10; irreducible, of rectum, 305.
Prolapsus uteri, new operation for, 793.
Prophylactic for scarlet fever and diphtheria, 699.
Prophylaxis; of puerperal eclampsia, 375; of phthisis, 563.
Proptosis, unilateral, boy with, 807.
Prostatic disease and bicycle, 384.
Pruritus; cause of, 27; ani, 250; linseed oil in, 282; and urticaria, 314; cutaneous, glycerole for, 315; pudendi, treatment of, 456; ani from use of coffee, 792.
Prurigo, 113.
Pseudo-leucæmia; red corpuscles in, 53: epilepsy, case of. 742.
Psoriasis vulgaris. 759.
Ptomaines, 494; poisoning by, 703.
Ptosis, new operation for, 306.
Pudendal nerve, neuralgia of. 599.
Pudic nerve, neuralgia of, 278.
Puerperal; aphasia, 56; tetanus, 248; eclampsia, phlebotomy in, 313; peritonitis, hot baths in, 342; convulsions, venesection in, 345; fever, 347; and erysipelas, 21; eclampsia, prophylaxis, 375; state and scarlet fever, 489.
Pulmonary; thrombosis, death from, 175; diseases, acetate of copper in, 186; fibroid, phthisis, 246: tuberculosis, 467; phthisis and ovarian disease, 730.
Pulse readings, 599.
Pump for stomach irrigation, 210.
Purgatives, new, 501.
Purpura hæmorrhagica, 153, 626, 695.
Pyo-salpinx, 747; double, 616.
Pyrexia, antipyrin fn, 700.
Pyriform sinus, lymphoid growth in, 426.
Pyrophosphate elixir iron, 441, 498.
Psychological curiosity, 349.

Quack convention, 318.
Quackery in France, 190.
Quarantine, Japanese and, 733.
Quinine; hypodermic solution of, 57, 251, 569; in whooping-cough, 113, 313; morphia taken for, 396; manufacture of, 440; injections in ague cake, 468, 631; in intermittent fever, 568; rash, case of, 699; substitute for 810.

Rabid animals' bites, cantharides in, 730.

Rabies, 344; microbe of, 18; treatment of, 307.
Radical operation for hernia, 115; cure of varicocele, 115; cure of hernia, 279.
Raphania, 21.
Rare form of disease, 238.
Recovery from alopecia of scalp, 25; of chronic insane, 280; from ascites, 303.
Rectal disease; diagnosis of, 133; cancer, operation for, 281; injections of medicated gases, 601.
Rectum; etherization by, 88; gaseous medication per, 279; irreducible prolapse of, 305; ulceration of, 594; fissures and ulcer of, 801.
Recurring attacks of chilliness, 143.
Red ants in vagina, 25; and leucorrhœa, 346; blood corpuscles, absorption of, 663.
Reflex or myelitis paraplegia, 154; nasal cough, 340; pain, 504.
Remedy; lanolin an old, 24, 26; for coryza, 57; for rose cold, 123; Chinese, for hydrophobia, 123.
Remedies; remote effects of, 374; for coryza, 603.
Removal of tumors, 51; of ovaries, 85, 524, 563; of fibro-cystic tumor, 137; of fallopian tubes, 146; of hairs, electrolysis for, 214; of callus by galvanic current, 401; of croupous exudation, 474; of gall-stones, 523; of uterine appendages, 649; of scapula for osteo-sarcoma, 691; catheter from bladder, 728; cancer, diagnosis of, 430; inflammation from terebene, 507; of tumor from cerebellum, 762; of ovary, influence of, 779; of fork from stomach, 782.
Renal surgery, cases of, 801, 811.
Report your cases, 566.
Reputation, look out for your, 277.
Resection of lung, 50; of rib for gangrene, 400; of gunshot wounds of joints, 625; of entire shaft of tibia, 755.
Respiratory muscles, paresis of, 408.
Resorcin, value of, 410.
Restoration of sight by fall, 397.
Retraction of penis, 400.
Retro-peritoneal glands, tuberculosis of, 205.
Reunion of cut-off fingers, 528.

Suturing of tendon, 643.
Sweating; unilateral, 299.
Sweats of phthisis, 504.
Swelling of knee, 249.
Symptoms of locomotor ataxy, 17; of pneumonia, 90.
Syncope in hot baths; danger of, 627.
Synthesis; manufacture of quinine by, 440.
Syphilis; universality of, 89; syrup trifolium comp in, 114; treatment of, 122, 179; influence of, 154; acquired, 155; node on tibia without, 239; statistical researches in, 338; at Nishni Novgorod, 348; and leprosy, 374; injections of calomel in, 439; in pregnancy, 465; hereditary microbe in, 470; secondary, 712; from vaccination, 729.
Syphilitic; hereditary, disease, 86; patches, 238; iritis, treatment of, 250; chancre of eyebrow, 312; chorea, 432; epilepsy, diagnosis of, 503; affections, treatment of, 568; ulceration of larynx, 673.
Syphilitica laryngitis ulcus, 673.
Syphiliticum erythanthema, 498.
Syphiloderm, tinea versicolor and, 367.
Syrup trifolium comp. in syphilis, 114.
Syzygium jambolanum in glycosuria, 627.

Tabetic, contracture of the old, 22.
Tæniafuge, pomegranate bark a, 423.
Tampon, a strange, 282.
Tapeworm; wandering, 403; treatment of, 491; how do quacks expel? 795.
Tapeworms, artificial, 512.
Tartar emetic, effect of, 723.
Tea-making, Chinaman in, 92.
Teeth; diseased, suppuration from, 24; decay of, 543; from medico-legal aspect, 797.
Teetotaler's fatal mistake, 126.
Temperance; drinks, 63; sensible view of, 702.
Temperature; in children, 409; in belladonna poisoning, 567.
Terebene; renal irritation from, 216; inflammation from, 507.
Termination of insanity, 260.
Test, performing Heller's, 346.
Testicle, dislocation of, 567.
Testicles, death from blow on, 406.
Testing, albumin, nitric acid in, 497.
Tests; for albumen in urine, 121; for purity of milk, 431.
Tetanus; treatment of, 48, 153; sedatives and electricity in, 152; traumatic, treated by rest, 211; puerperal, 248; rheumatic, pilocarpine in, 700; equine, origin of, 719.
Tetany, diagnosis of, 339.
Teutonic complexion, 560.
Thallin; in enteric fever, 180; action of, 442.
Therapeutic; notes, 479; value of mineral springs, 638.
Therapeutical inheritance, 591.
Therapeutics; hygienic, 161, 193; of chloride of sodium, 273; in newspapers, 606.
Thermo-cautery in herpes, 553.
Thermometer, clinical, novel form of, 779.
Thigh, amputation of, 337.
Thinking and working, 223.
Thoracic aneurism, treatment of, 90.
Thorax, malformation of, 22.
Thread-worms, expulsion of, 731.
Thrombosis, pulmonary, death from, 175.
Tibia; node of, 239; resection of, 755.
Tibiæ, inequality in length of, 24.
Tinea; versicolor and syphiloderm, 377; tonsurans, 569.
Tincture of chloride of iron in miscarriage, 308.
Tinnitus aurium, electricity for, 251.
Tobacco; in Europe, consumption of, 414; amblyopia, 713; muscular rheumatism from, 763.
Toe-nail; ingrowing, 282; ingrowing, treatment of, 730.
Toilers among dead, 284.
Tongue; tubercular ulcer of, 493; tuberculosis of, 506; black, 557; fissures of, 694.
Tonics in malarial hæmaturia, 410.
Tonsils, function of, 283; congenital defect of, 807.
Tonsillitis; paralysis after, 537; in adolescents, 595.
Tonsillotomy, hemorrhage after, 280.
Tooth; powders, 666; boric acid, 311; extraction, cocaine in, 506.
Toothache soother, 667.
Tossed by Spanish bull, 126.
Trachea; plugging of, 370; papilloma of, 442.
Tracheotomy; substitute for, 362, 393; removal of croupous exudation after, 474; for membranous croup, 780.
Trachoma, crushing of granulations in, 343.
Transfusion of saline fluids, 506.
Transmission; of yellow fever, 563; of nervous phenomena, 753.
Traumatic; tetanus, 48; treated by rest, 211; treatment of, 312; pleurisy, 473; stricture, treatment of, 275; pneumonia, infectious or, 661.
Traumatism, neuritis following, 147.
Tremens, delirium, 45.
Treatment; of cirsoid aneurism, 24; of uterine cancer, 25; of diabetes, 25, 315; of tetanus, 48; of chronic ulcers, 50; of furunculosis, 57; of obesity, 79; of burns, 87; of pleuritic effusions, 87; of facial neuralgia, 89; of thoracic aneurism, 90; of hysteria, 91; of wounds, 97: of carbuncle, 109, 282; of acute dysenteries, 112; of whooping-cough, 113, 150, 270, 667; of lacerated cervix, 114; of diphtheria, 121, 411, 439, 721; of idrosis simplex, 135; of neuritis, 147; of syphilis, 122, 179; of sciatica, 182; of diarrhœa, 183, 664; of urethral stricture, 184; of strictures, 187; of diseases, 190, 646, 732; of

flexions, 206, 232; of chronic gastritis, 209; of traumatic tetanus, 211, 312; of orchitis, 241; of epididymitis, 241; of hemorrhoids, 244; of fracture humerus, 247; of cholera, 250; of sypilitic iritis, 250; of traumatic stricture, 275; os somnambulism, 280; of irreducible prolapse of rectum, 305; of rabies, 307; of miscarriage, 308; of bruises, 313; of aphthæ of vulva, 314; of chronic metritis, 340; of anæmia and chlorosis, 346; of singultus, 347; of endocarditis, 348; of cystitis, 355; of irritable brain, 367; of subinvolution, 367; of buboes, 371; of goitre, 376; of typhoid fever, 377, 437, 527, 773; of cataract operations, 397; of sick-headache, 410; of cirrhosis of liver, 410; of adenitis, 411; of urinary incontinence, 427; of chronic abscesses, 435; of abdominal wounds, 441; of profanity, 447; of pruritus pudendi, 456; of intermittent fever, 461; of pelvic hæmatocele, 466; of perityphlitis, 483; of nasal catarrh, 488; of tape-worm, 491; of membranous dysmenorrhœa, 505; of gunshot, 530; of catarrhal icterus, 534; of acute gonorrhœa, 535; of venereal bubo, 535; of chronic cystitis, 536; of hepatic abscess, 537; of trichinosis, 538; of fractures, 539; of herpes, 553; of disease by Kaffir's, 555, of strangulated hernia, 557, 562, 669; for fatty placenta, 564; of salivation, 566; of syphilitic affections, 568; of uterine diseases, 568; of acne, 569; of gleet, 570; of chorea, 577; of spina bifida, 592; of pseudo-membranous croup, 595; antiseptic, 607; of subinvolution of uterus, 624; of glaucoma, 666; of diarrhœa in children, 666; of sciatica, 667; of phthisis, 667; of hemorrhoids, 687; of lupus, 696; of thread worms, 697; of felon, 700; of hernia, 724; of ingrowing toe-nail, 730; of membranous dysmenorrhœa, 731. of tubercular meningitis, 792; of fissures and ulcers of rectum, 801.

Tri-bromide of allyl, 569.

Trichinosis, treatment of, 538.

Trifolium syrup in syphilis, 114.

Trigger finger, 12.

Trophoneurosis of skin, 402.

Trusses, badly made, 247.

Trypsin in diphtheria, 90.

Tubercular; ulcer of tongue, 493; meningitis, 717, 792; inoculation, 760, 793; ulceration of vagina, 792.

Tubercle bacilli; in Addison's disease, 48; in supra-renal capsules, 471; and heredity, 472; staining of, 694.

Tuberculosis; of retro-peritoneal glands, 205; of skin, 407; pulmonary, 467; of tongue, 506.

Tumor; of uterus, 107; removal of, 137: enormous, 312; ovarian, 361; cerebral excision of, 559; ovariotomy for, 588; fibro-sarcomatous, 618; removal frem cerebellum, 762; of eyeball, 781; vomiting a water, 786; epitheliomatous, of cæcum, 810.

Tumors; removal of, 51; scrotal diagnosis of, 429; scrofulous, 537.

Turkish confinement, 59.

Turpentine oil; in scrofulous ozæna, 410; an antidote, 506; in diphtheria, 539.

Twin, labor completed, 722.

Twins, case of, 121; astigmatism in, 779.

Tympanites in hysterical women, 472.

Typhoid fever, 321; cardiac changes in, 25; etiology of, 245, 453; bacillus of, 251; contagiousness of, 294; treatment of, 377, 437, 527, 773; prevent falling of hair after, 732; recrudescence of, 443; pathological specimens, 483; walking, 744.

Ulcer; gastric, 376; tubercular, of tongue, 493; shoemaker's, 698; circular gastric, 727; of rectum, treatment of, 801.

Ulcers; iodoform and nitrate of silver in, 122.

Ulceration of rectum, 594; syphilitic of larynx, 673.

Ulexine, 568.

Umbilical cord; prolapse of. 10; velamentous insertion of, 601; cord round neck of child, 762.

Unalterable cocaine solutions, 346.

Undeveloped sexual organs, 807.

Unilateral sweating, 299; proptosis 807.

Unnatural mother, 671.

Ununited fracture of humerus, 247; of patella, 249.

Uranostomatoscopia frenopatica, 665.

Urates; removal of, 228.

Urethra; female, rupture of, 17; examining the 90; chronic abscess of, 185; electrolysis in stricture of, 372; penile, pouch of, 696; lupous stricture of, 763.

Urethral stricture; treatment of, 184; electrolysis in, 552.

Urethram, calculus removed from, 369.

Urethan in neutral diseases, 562.

Urethritis; rheumatic, 313.

Urinary fistula, 346; incontinence, 427; difficulties in boys, 595; urine tests for albumen in, 121; extravasation of, 266; labor by suppression of, 378.

Urticaria, 538, and pruritus, 314.

Uteri cervix; dilatation of, 56; lacerations of, 264; epithelioma of, 326; carcinoma cervicis, 46; inertia, cause of, 347; prolapsus, new operation for, 793.

Uterine cancer; treatment of, 25; cavity, photographing the, 94; cancer, diagnosis of, 104; extra pregnancy, 201; disease, cardiac neurosis in, 307; fibroid, ergot in, 346; galvano-cantry, 440; fibroid, 524; diseases, treatment of, 568; disease, 727; injection, death from, 633; appendages, removal of, 649; catarrh, bichloride of mercury in, 787.

Utero, acute pneumonia in, 729.

Uterus; rupture of, 18, 594; tumor of, 107; supra-vaginal amputation of, 332; foreign substance in, 371; acute inversion of, 526; faradization of, 567; fibroid polypus of, 622; treatment of subinvolution of, 624; castration in, 633; fibroid of, 649; double, 665; during pregnancy, rupture of, 790.

Uvula, excision of, 88.

Vaccine in mushroom jelly, culture of, 285.

Vaccination; utilizing mosquito in, 222; with animal lymph, 309; skin disease from, 560; syphilis from, 729.

Vagina, double, 51, 665; tubercular ulceration of, 792.

Vaginismus, 365.

Vaginitis, case of, 25.

Valvular disease, 274, 417.

Variola contagiousness, 409.
Varicocele, radical cure of, 115.
Varicosed labial veins, rupture of, 722.
Vaso-motor neucrosis, 86.
Vegetables, birth-places of, 286.

W. H SCHIEFFELIN & CO'S.,

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

105-15556

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

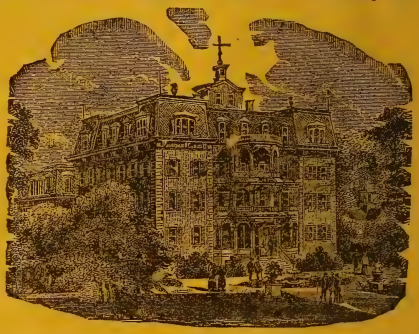
An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease-producing matter.

INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,
36 Platt St., New York.

BURN-BRAE.



This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful HOME.

MALARIAL HÆMATURIA.*

BY J. A. STAMPS, M. D.,

Of Wallaceburg, Ark.

This is a remarkable affection, and one about which all of the text-books which have been at my command say very little. It is characterized by the occurrence of one or more rigors, followed in the course of a few hours by a discharge from the kidneys of urine loaded with blood. It seems to have been tolerably clearly known as early as 1832 by Elliotson (in *London Lancet*, 1832, p. 500), while an article appears in the *Medical News and Hospital Gazette* of New Orleans, by an unknown author, in which he dates a case of hæmaturia as far back as 1820, and in his remarks on that and other cases, says: "Whether hæmaturia, more than epistaxis, menorrhagia, or any other of the bloody profluvia, be the result of that bugaboo, miasmata, is questioned," yet from the fact that it occurred in a miasmatic region (Mississippi), as he admitted, and at a time of the year (September) when the various manifestations of malarial poisoning are most prevalent, one would readily infer that it was strictly of malarial origin.

Notwithstanding the occurrence of cases at so early a period, the first complete report of an undoubted case was not published till 1854, by Dressler (in *Virchow's Archiv.*, Bd. 6, S. 264, 1854).

The majority of the vast number of cases which have been reported in the different medical journals and periodicals have occurred in persons living near low-lying marshy ground, often situate upon rivers or lakes, and from the fact that in every instance of the literature that is in my possession regarding the matter, the cases have occurred at a time of year when other malarial affections were most prevalent, and that the most virulent and intractable forms of this disease occur in districts the subject of other malignant forms of malaria, and again, from the fact that a majority of the persons attacked give a history of having been the subjects of some form of ague for a period of time varying with each case, I am led to look upon malaria as the main factor in its causation.

There is in this disease (as is the case in inter- and remittent fevers) two degrees of intensity, to wit, a mild form in which all the symptoms are of only moderate intensity, and quite a number of symptoms hereinafter to be described are absent, and a more malignant form, in which all of the symptoms are of an aggravated character, and attended with great prostration, etc. This latter seems to be most frequently met with in the Southern States of our country, and in fact in all countries the subjects of other malignant forms of malarial diseases. In neither degree of the disease is it essential that the red blood corpuscles should be present, as they may be represented by their coloring matter, hæmaglobin, hæmatin, alone or in conjunction with all the constituents of a blood cell in a degenerated state.

In speaking of hæmaglobin in his Physiology, p. 429, Foster says: "Since it is soluble in serum, and since the identity of the crystals observed occasionally within the corpuscles with those obtained in other ways,

* Read before the Hempstead County Medical Society.

shows that the hæmaglobin, as it exists in the corpuscles, is the same thing as that which is artificially prepared from blood, it is evident that some peculiar relationship between the stroma and the hæmaglobin must, in natural blood, keep the latter from being dissolved by the serum. Hence, in preparing hæmaglobin, it is necessary, first of all, to break up the corpuscles." Now, as corpuscles are rarely detected in the urine of these cases, it is evident that some unknown morbid principle is brought to bear on the corpuscles, which proves fatal to their identity as such before they reach the microscopist.

As the treatment of the two varieties is pretty much the same (the milder form of course requiring less heroic measures than the malignant), and from the fact that the malignant type is so much the more important of the two, a careful study of that form will be of most interest to us.

Of three cases occurring in this vicinity during the past year, two were males; and from the reports of quite a number of cases coming into my possession, I find that its preference for males over females is as four to one.

Symptoms.—As before stated, they are usually able to recall a history of exposure to malaria, and the majority of cases have suffered from more or less distinct attacks of inter- or remittent fever. Some patients complain of an aching in the loins, uneasiness in the region of one or both kidneys, and a feeling of fullness in the stomach and lower part of abdomen for some time prior to the attack, or the attack may be ushered in by a rigor of varying intensity, the patient complaining of chilliness and a dull dragging pain across his loins, the latter condition speedily passing into a more or less severe aching, and an uneasy sensation of fullness in the region of one or both kidneys and lower part of abdomen, attended with pallor or duskiness of surface, shrinking of skin, pinched features, and severe rigors, together with which there is usually a feeling of weakness, aching of limbs, extreme nausea and vomiting, retraction of testicles, yawning and respiration modified after the order of sighing. Pulse accelerated, small, and compressible. Temperature at the beginning may be subnormal, but in a few hours rises to from 100° to 105° F. There may be diarrhœa or constipation.

After the patient has been in this condition for a period of time varying from half an hour to four or five hours, he is very much astonished to find on passing water that the fluid is of a very dark color, varying from a bright wine to a porter or black color. The discharge of this peculiar-colored urine may be intermittent or continuous.

In a very short time the skin of the entire body assumes a deep yellow color, and continues thus till there is a decided improvement in the general condition of the patient, and till the urine is free from the coloring matter.

Some attribute this to a disturbance of the hepatic function and a dissemination of the bile pigment through the system, while I am of the opinion that it is due to the presence of the coloring matters of the blood which have escaped into the tissues in small quantities. We well know that during the course of an injury to any part of the cutaneous system with an extravasation of blood, the tissues assume a yellow hue, and in this disease there is a striking resemblance to the yellow color left by a bruise with an extravasation.

Foster's Physiology, p. 434, in dealing with hæmaglobin, writes: "In the unreduced hæmaglobin or oxyhæmaglobin, the potent yellow which is blocked out in the reduced hæmaglobin makes itself felt so that a very thin layer of hæmaglobin, as in a single corpuscle seen under the microscope, appears yellow rather than red."

Green's Pathology, page 100, in speaking of pigmentation, says: "Soon after the extravasation has taken place, the hæmaglobin escapes from the red blood corpuscles, either by exudation or by destruction of the corpuscles, and mixed with the liquor sanguinis, infiltrates the surrounding tissues."

Green's Pathology, page 101, in speaking of the different methods by which hæmaglobin infiltrates the tissues, says: "In whichever of these ways the hæmaglobin is derived it infiltrates the tissues, staining both the cells and intercellular substance of a yellowish or brownish-red color.

"Besides, hæmatoiden, which is derived from hæmaglobin, appears to be closely allied to the coloring matter of the bile, bilirubin, which is also a derivative of hæmaglobin. It exhibits similar reactions when treated with concentrated mineral acids, displaying the same variations of green, blue, rose, and yellow colors."

By consulting Foster's Physiology, p. 57, you will find the following, to wit: "But hæmatoiden, not only in the form and appearance of its crystals, but also as far as can be ascertained by the analysis of the small quantities at disposal, in its chemical composition is identical with bilirubin, the primary pigment of the bile."

Thus we can readily see how any one, no matter how careful in testing, may err by supposing the peculiar discoloration due to bile instead of blood coloring matter.

Physical and Chemical Characters of the Urine.—The urine is usually acid in reaction, rarely alkaline, though it may be neutral. In some cases almost odorless, in others very offensive. Specific gravity varies between 1010 and 1030. It always contains the blood coloring matters in a varying quantity, which colors the urine from a slight tinge to an almost black hue, the darker color being characteristic of the more malignant form of the malady. A test for the presence of blood consists in adding to a small quantity of the urine a few drops of a mixture of equal parts of trs. turpentine and guaiac., which if blood be present imparts a blue color to the mixture. The urine upon standing for a short while throws down a deposit varying in quantity according as the amount of coloring is small or great. This sediment consists principally of a large quantity of albumen, together with granular and hyaline casts of the uriniferous tubules, and probably granular urates and crystals of oxalate of lime, but in place of blood corpuscles (which are rarely found, and if detected are in small numbers), presents abundant brownish granular matter, which is certainly the result of a retrograde metamorphosis of the red blood corpuscles, for by applying micro-chemical tests, the blood-coloring matter can be detected beyond a doubt.

If a strong solution of hæmaglobin be treated with acetic (or other) acid, a brown color is observed from the appearance of hæmatin, and upon adding ether to the mixture and shaking the hæmatin rises into the supernatant ether, which it colors a dark red, and which examined with a spectroscope is found to possess a well-marked spectrum, the so-called acid hæmatin spectrum of Stokes.

Another test for yielding Teichman's hæmin crystals consists in placing a drop of the sediment upon a glass slide of a microscope, and allowing it to dry, then mix thoroughly with a few bits of sodium chloride, and cover with a glass or mica cover, under which allow two or three drops of glacial acetic acid to pass; now carefully warm the slide for a few seconds over a spirit lamp, and when most of the acetic acid has evaporated, examine microscopically. If proper care has been taken in preparing it, and if the blood-coloring matter be present, hæmin crystals will be seen forming as the mixture cools.

Prof. James Tyson, of Philadelphia, in a paper read before the Pennsylvania State Medical Society for 1883, a reprint of which he kindly sent me, and for which I am greatly obliged, as it has been of much service to me in preparing this article, says in the matter of the presence or absence of blood discs, it is to be remembered that these may be present at the moment the urine is passed, but disappear by subsequent solution if the urine happen to be alkaline, or become so secondarily. It is an interesting fact, too, that the colorless blood corpuscles are often present intact, even when the red discs are absent.

Now, if we accept Hayyem's views of the origin of the red blood corpuscles; there would be nothing more conclusively proven than that the granular matter is derived from a degeneration of the red corpuscles; for we well know that very shortly after the urine is voided it begins to undergo decomposition, and during this process various chemical changes are wrought, and in this way the morbid principle above spoken of is produced, or this poison existing in the blood and acting on the corpuscles, as they are circulating through the vessels, proves fatal to a varying number of them previous to their escape from the vessels.

To determine the presence of albumen in the urine, it will be necessary to add to a quantity of urine in a test tube, and if the urine be not acid, render it so by adding a small amount of acetic acid and boiling. If albumen be present it renders the fluid cloudy, according to the amount present, which, when set aside, settles as a sediment. The height it occupies in the test tube forms an approximate estimate of the amount of albumen present (it would be well enough to add a drop or two of nitric acid after boiling, to insure the solution of any earthy phosphates which may have existed). The quantity of albumen will vary from a mere trace to as much as one-half of the entire quantity of urine passed, and some allowance will have to be made as to the quantity in these cases, as the coloring matters of the blood are carried down with the albumen.

As these are the most important abnormal constituents of the urine in this disease, it will not be necessary to say more on the subject, so we will now turn our attention to the pathology, which is somewhat obscure, and as I can find nothing very definite nor elaborate regarding its pathology, my deductions will be from a wholly theoretical standpoint.

It has been regarded by some as a disease of the blood alone; others say that it is an affection exclusively of the kidneys, while

yet a third class are of the opinion that it is a disease of the blood and blood vessels impairing the integrity of both—and with this latter class I fully agree. To say that it is a disease of the blood alone would be far short of explaining the cause of the kidneys alone being the subject of such a profuse hemorrhage; and on the other hand to say that it is solely an affection of the kidneys would lead us to equally as great an error in accounting for the peculiar yellow discoloration of the skin of the entire body, which condition is undoubtedly due to an abnormal condition of both blood and blood vessels.

Mr. Green, in his admirable work on Pathology, in speaking of pigmentation, page 100, says all true pigment is derived from the blood, and in another place he says, "In the pathological process also, the pigment is derived from the same source, although its presence in the tissues is rarely dependent upon any abnormal secreting powers in their cellular elements, but is usually the result of certain changes in the circulation or in the blood vessels, owing to which the coloring matter of the blood escapes and infiltrates the surrounding parts."

Now, the fact that in persons the subject of ague there is degeneration of red blood corpuscles resulting in the formation of pigment granules, shows very clearly that there is an abnormal condition of the blood; and these granules being carried through the circulation and acting directly on the blood vessels eventually, when in sufficient quantities and long-continued, induce an unhealthy state of the blood vessels also.

For a proper understanding of this peculiar affection we will necessarily have to turn our attention for a while to a consideration of some of the pathological processes of other forms of malaria. The result of the action of malarial poison probably varies a good deal, according to the idiosyncrasy of the individual attacked, as well as the amount and degree of virulence of the poison itself. Just as in some individuals a moderate dose of morphine produces quiet repose, while in others it causes extreme wakefulness and restlessness, so may this poison excite now a disturbance of innervation, now a disturbance of circulation. The only constant lesion discoverable after death from malaria is enlargement of the spleen. This organ becomes distended with blood to many times its normal size, and if the patient die when the attack is recent, it is found to be large and congested; the liver, too, is commonly, to some extent, enlarged and increased in bulk.

Congestion of neighboring parts of the alimentary canal has also been observed, and it may be added that in hemorrhagic cases traces of hemorrhage at mucous surfaces and beneath the serous membranes may be discovered.

Enlargement and induration of the spleen and liver are among the most common results of long continued or repeated attacks of ague, or of long residence in malarious districts.

Another change to which these organs are liable is a peculiar dark or slaty discoloration due to disintegration of blood corpuscles and their conversion into pigment granules.

In the liver this is generally referable to the changes which occur in minute extravasations of blood into the capsule of Glisson, and the hepatic parenchyma in the spleen to similar changes going on in the blood which occupies the intermediate blood-passages.

The pigment is apt to escape from the spleen and enter the general circulation and become arrested in the capillaries of different organs, more especially the liver, brain, and kidneys, and thus not only cause them to become pigmented, but interfere more or less with their nutrition, and thus induce various organic and functional disturbances. Now, why the poison acts as it does and upon what particular organ or organs it acts, is not positively known; but from the various disturbances caused by it there is good reason to believe that (whether it is by direct or indirect action) its main effects are produced through the agency of the sympathetic system of nerves; and from the various troubles, as diarrhœa, dysentery, splenic and other enlargements produced, we are led to the conclusion that the action of malaria on the vaso-motor centres is mainly paralyzing. The disturbances which shall engage our attention will be those concerned in the circulation.

Supposing the heart to act normally, it is obvious that with a constant blood mass the total capacity of the vascular system must be kept within certain limits. It may easily dilate so as to contain all the blood (as the abdominal veins alone would do after section of the splanchnics), when the heart would receive none, or the arteries may contract so as more or less completely to stop circulation by driving all of the blood into the veins. Now between these two extremes there is a state of the vascular system corresponding to any given heart force, which is most favorable for the circulation. This is normal tonus. It is the province of the vaso-motor system of nerves to maintain this re-

lation between the heart and its vessels. Enlargement of the vascular system, whether due to general or local diminution of vascular tonus, slows circulation.

Diminution of capacity of the vascular system in moderation would, as a matter of course, quicken it in cases of local increase of tonus; the blood, which the more or less anæmic part should contain, is thrown into the system at large, and raises blood-pressure until the vaso-motor system causes other vessels to dilate compensatorily so as to receive both their own blood and that of the contracted vascular area.

Arterial tone, then, both general and local, is a powerful instrument for determining the flow of blood to the various organs and tissues of the body, and thus becomes a means of indirectly influencing their functional activity.

Far more important, however, than the maintenance of a normal tone, which, indeed, might at once and forever be arranged by the proper natural calibre of the elastic blood-vessels, is the power which the central nervous system possesses of varying the tone of this or that artery, or group of arteries; of increasing it or of diminishing it if producing constriction or dilatation, and of thus affecting changes in general or local blood-pressure, or in both, and consequently of determining a flow of blood in this or that direction according to the needs of the economy. And the exercise of this carefully-arranged manipulation of the muscular walls of the arteries may be called forth in either direction in the way of constriction or dilatation by means of nervous impulses, either originating in the central nervous system itself or started by afferent impulses passing up to the central nervous system from some sentient surface.

The presence of pigment granules which enter the circulation from the spleen and liver and are carried by the blood current to the various organs, principally the brain and kidneys, by acting on the central nervous system induces disturbances of the circulation, besides the local effects produced upon the vessels of different areas by their presence. Foster's Physiology, p. 263, says: "It is more than probable that many substances introduced into the blood, or arising from natural or morbid changes, may affect blood-pressure by acting directly on the nervous centres."

We are all well aware of the fact that though a local tone may exist independently of the central nervous system, the condition of the numerous vascular areas in the living body in a normal condition is arranged and variously modified in order to meet the passing demands or permanent needs by the central nervous system through the agency of the vaso-motor nerves.

Foster's Physiology, p. 276, writes thus: "The tone of any given vascular area may be altered positively in the direction of augmentation (constriction), or negatively in the way of inhibition (dilation), quite independently of what is going on in another area. The change may be brought about by (1) stimuli applied to the spot itself and acting either directly on some local mechanism or indirectly by reflex action through the general central nervous system; (2) by stimuli applied to some other sentient surface and acting by reflex action through the central nervous system; (3) by stimuli (chemical blood stimuli) acting directly on the central nervous system."

Now, in this condition we know that during the rigor the cutaneous vessels are constricted, and no fact in the economy of man is oftener or more strikingly brought home to us than the close relation existing between the skin and kidneys as far as their secretions and blood-supply are concerned, and this relation undoubtedly seems to be under control of and maintained by the vaso-motor system of nerves; thus, when the skin is cold and pinched its blood-vessels are, as we know, constricted, and by this causing an increase in the general blood-pressure, and this leading to compensatory dilatation of the arteries of other vascular areas, and from the fact of the close relation existing between the skin and kidneys, it is clear that the renal vessels would dilate and an augmentation of the flow of blood through these vessels would be the inevitable result.

Now, taking it for granted that there is a paresis of the vaso-motor nerves supplying the kidneys, we would expect an increased flow of blood greatly in excess of the amount which would otherwise occur; and in addition to this, the presence of pigment granules in the blood would be capable of bringing about an abnormal condition of the blood-vessels; and admitting it as proven that there is an increased flow of blood to the kidneys, and from the fact that they are largely concerned in the removal of the effete substances from the blood, we would naturally expect to find a somewhat greater amount of pigment in the blood going to these organs; and this, by acting directly on the renal vessels, would, if in sufficient quantities and long continued, greatly impede the circulation through them, and cause a consid-

erable amount of irritation. Thus, by the impediment to the flow of blood there would be a slowing of the circulation, and still further dilatation of the vessels, and from the irritation caused by the granules there would be an attempt made by the secreting epithelium to throw them out of the circulation.

Foster, in his Physiology, p. 575, in speaking of the artificial excitement of the flow of urine, by injecting urea, etc., into the blood, says: "The most natural way of explaining the phenomena is to suppose that the presence of the substances in the blood excites the renal epithelium to an unwonted activity, causing them to pour into the interior of the tubules a copious secretion, just as the presence of pilocarpine in the blood will cause the salivary cells to pour forth their secretions into the lumen of their ducts. Thus we are led to the conclusions that the so-called malarial poison acting on the blood causes either an abnormal formation of pigment or degeneration of the red blood corpuscles and their conversion into pigment-granules, and that these circulating through the vaso-motor and other nervous centres set up an unhealthy condition, and if in sufficient quantities, or long enough continued, results in a paresis of these centres, particularly those centres governing the internal organs, and furthermore, that the pigment granules (as well probably as the malarial poison) acting as an irritant to the blood vessels, cause them, after a varying period of time, to lose their power of retaining the blood coloring matter. And again, as it is the office of the kidneys to remove these waste products from the blood, and from the fact that their secreting activity is more markedly affected by the amount and condition of the blood passing through them than most any other organ, or from a peculiar idiosyncracy of the individual, the brunt of the mischief falls on the kidneys.

(*To be continued*).

DEDUCTIONS FROM NINETY-ONE (91) CASES OF RHEUMATISM.*

BY WILLIAM A. EDWARDS, M. D.,

Member of the Committee, Instructor in Clinical Medicine and Physician to the Medical Dispensary in the University of Pennsylvania, Physician to Saint Joseph's Hospital, etc., etc.

The study of disease by the collective method is of value in direct proportion to the number and character of the replies that are received. When we compare the report of the above committee to that of the committee of the British Medical Association, in which, for instance, 1066 cases of pneumonia are tabulated, it will at once become apparent how extremely valuable these reports may be made when vast numbers of cases are recorded from which reliable conclusions can be derived; still a careful perusal of these ninety-one cases will amply repay one for the time and thought expended.

Sex appears to have presented a direct predisposing cause to the disease, as of the cases reported 58 were males and 32 females,* thus again establishing the well-known statement of the books that acute rheumatism is more frequent in men than in women, an undisputed fact for many years, as Hippocrates in his *Aphorisms* states that women are less liable than men; but as we shall see later, the report seems to disprove the statement that this is due to the fact that men are more exposed to the influences producing it, and not because of a greater susceptibility to the disease; we shall also see that the greatest number of cases are recorded among "housekeepers," an occupation in which it would be an extremely difficult matter to establish any special relation to rheumatism. Again, among the males we find that the greatest number of cases are recorded among "farmers," once more a business that is not nearly so exposed as others recorded in the report, and would not seem to offer such a predisposing environment as, for example, an "ironmonger," a "puddler," a "miner," or a "daily laborer." It would most certainly seem that an occupation that entailed protracted exposure in damp apartments (miner), or exposure of the body to cold or wet when in a perspiring state (puddlers), would be a decided exciting cause; yet the report does not bear this out, but it does show in a striking manner the frequency with which rheumatic attacks follow ordinary exposure to cold or to chilling the superficies of the body in those of the rheumatic diathesis.

The rationale of these attacks would seem to be that during the use of the body, *i. e.*, the muscles, lactic acid and acid potassium phosphate are produced, and when the body is chilled, the elimination of these matters is stopped, hence an accumulation occurs, and with it the resulting rheumatic outbreak. It is proper to state, however, that Reyher† does not regard the accumulation of the acid in the blood as a cause of rheumatism,

*Being a consideration of the report of the Committee on the Collective Investigation of Disease of the Medical Society of the State of Pennsylvania.

*One case sex not stated.

†Virchow's Arch., vol. xxi., p. 85, quoted by Bartholow.

Prout and Richardson, however, are as firm advocates of the affirmative side of the question, the latter having demonstrated the fact that injections of lactic acid are followed by endocarditis, and that its medicinal administration in diabetes has in various instances apparently caused a rheumatic inflammation of the joints.

The relation of the *use* and *abuse of alcohol* in its various forms to the disease is of sufficient importance to claim our attention.

While the returns in this matter are not as full or concise as we all would desire, still they are sufficient for the purpose, and show that restriction in the use of alcoholic stimulants is requisite to the welfare of a rheumatic. Sir Thomas Watson so aptly remarks that the instances are not few of men of good sense and masters of themselves, who, being warned by one visitation of the gout, have thenceforward resolutely abstained from rich living and from wine and strong drink of all kinds, and who have been rewarded for their prudence and self-denial by complete immunity from any return of the disease, or upon whom at any rate its future assaults have been few and feeble. "I am sure it is worth any *young* man's while who has had the gout to become a teetotaller."

To return to the report, we find that four (4) of the males are recorded as "intemperate," and that none of the females are so recorded. Thirty-four cases are stated to be "total abstainers," and fifty-one cases "temperate." The nature of the attack in these cases would show to a certain extent the effect or non-effect of alcohol upon the disease.

Of the total abstainers, we find that eleven were subjected to a moderate attack and thirteen to a severe. Of the fifty-one temperate cases, twenty had a moderate attack and thirty-one a severe. Of the alcoholics (four) one had a moderate attack and three a severe.

In one temperate case and in one total abstainer the nature of the attack is not stated.

To consider this matter more closely, we notice an apparent contradiction in the fact that of the non-alcoholics nearly twice as many are noted to have had a severe attack as compared to those recorded as "moderate;" this is due to the small number of returns, as when we compare the nature of the attack in the intemperate, we find the ratio of severe to moderate as *one* is to *three*.

It seems, then, to be established, by this report, that over-indulgence in alcoholic liquors will, if associated with certain other conditions already referred to, undoubtedly give rise to or be a decided ætiological factor in the production of an acute attack of rheumatism.

It does not seem to be of much importance which of the liquors are used, but the amount of alcohol contained therein is of great significance. The mischievous effect of liquors appears to be in direct proportion to the amount of alcohol which they represent; it is a somewhat general statement that the stronger wines, as port, sherry, and madeira, are much more injurious in this respect than the lighter wines, as hock, sauterne, or moselle. By many, malt liquors are considered the most injurious, but the question as to which is the most or least desirable is still *sub judice*.

An inquiry regarding the *food* elicits the fact that of the ninety-one cases, but one had "insufficient" recorded. This patient, a woman, æt. 46, housekeeper, had been exposed to wet and cold a few days before the attack, which was moderate in character, lasting ten days, from which she made a perfect recovery, with, however, a slight persistence of the disease in three joints.

The effect of climate upon the disease, as shown by the report, is that the greatest number of cases occur in "high, dry, exposed" localities, with the atmosphere "damp, wet, and cold," and with the wind blowing from either the west or northwest; this, remember, is the climatology of Pennsylvania alone in relation to the disease, as the cases are taken from the various towns, cities, boroughs, villages, and hamlets throughout the State.

Among the *predisposing* causes may also be added exposure to over-fatigue which occurred in sixteen males and five females; in four of the former and two of the latter the fatigue was sudden. Shock preceded the attack four times—three times in males and once in females.

Age appears to bear no particular relation to the disease, as the youngest case was nine months, and the oldest sixty years. Again, a severe attack is noted in a child æt. ten months, and a mild one in a man æt. sixty years. The investigation of the condition of the *peri-* and *endocardium* in the series of cases becomes indeed an interesting part of our study. The known tendency of the rheumatic poison to these membranes, let it be what you will, adds renewed interest to their consideration.

The condition of the circulatory apparatus was noted in twenty-four cases, an extremely small relative proportion, if it represents the true relation of the occurrence of cardiac complications in the ninety-one cases.

In fourteen instances was the pericardium attacked; twice was the mitral valve diseased. One observer notes "a distinct murmur during the attack, with apex beat lowered to seventh interspace." Four cases are recorded as having "heart disease, before, during, and after attack, with pericarditis, murmur, and lowering of apex beat." Two cases of murmur following the attack are placed on record. One case of pericarditis, which existed previous to the attack, was not apparently affected by the rheumatic complication. One somewhat extraordinary case is noted of "pericarditis only during attack, with lowering of apex beat."

The cutaneous system was but rarely affected; the following skin eruptions are recorded: Erythema 2, eczema 2, and one example of these eruptions: papular, blebs, herpes, sudamina, furuncles, roseola (after attack). Subcutaneous nodules are recorded as occurring but in seven (7) cases.

Without further comment upon special symptoms, we will proceed to a consideration of the methods of *treatment* pursued by the various observers. That most usually advocated is the general plan of therapeusis, comprised under the somewhat comprehensive term of "alkaline." Salicylic acid and the salicylates, followed by, or combined with quinine, seems to have been a very efficacious combination. Salicylate of ammonia is an alkali worthy of special mention, on account of the happy combination of the two drugs, particularly in asthenic cases. The iodide of potassium was exhibited in many cases with apparent happy results. One reporter is an advocate of frequent catharsis; another, of vapor baths. Again, we note the advocacy of cold sponge baths; leeches were also applied. The efficacy of dietetics was proven by the frequent happy recourse to a "milk diet." Mercurial inunctions and the faradic current in two instances appeared to prove beneficial. Tincture of the chloride of iron during convalescence, in many instances, apparently hastened a more speedy return to the normal blood crasis. An observer reports that "the rheumatic list in the materia medica" was exhibited to his patient without any apparent amelioration of the symptoms. Again, a plan of treatment styled as "antirheumatic," is reported. Opium was in many cases the keystone of the treatment; indeed, few cases are recorded in which the drug was not exhibited at some time during the course of observation.

The following drugs are reported as having been used with varying success, and upon scanning the list we will notice that the drugs exhibited are almost as numerous as the number of cases recorded: Digitalis, gaultheria, soda biborat., sulphite of soda, iron, cod liver oil, vin. colchicum, pulv. ipecac et opii, pot. carb., magnesia sulph., jaborandi, aconite, veratrium viride, nitrate, citrate, and acetate of potash, lemon juice, fluid extract cimicifuga, hydriodic acid, potas. et sodæ tart., hyoscyamus, gelsemium, mass, hydrarg., fl. ext. manaca, guiac. citrate lithia, sulph. codeia, coto bark.

1504 *Walnut St., Phila.*

COUNTER PRESCRIBING.*

BY MR. J. W. RIDPATH,
Of Jenkintown, Pa.

Having been appointed to present a subject for discussion, I have concluded to present one upon which we will not all hold the same views. One-sided debates are not usually very spicy. There are usually some points in which our views antagonize. To bring out these opposite views, and allow a free discussion from opposing forces, may benefit all parties in a manner similar to the rounding and polishing of pebbles by rubbing against each other.

Recognizing that a subject for discussion should have two sides, I have concluded to present the overlooked side of a subject much talked of by physicians, viz.: "counter prescribing."

After looking at the pros and cons of this subject for years, your correspondent is compelled to conclude that the subject is mostly agitated by persons not familiar with all of its difficulties; and who might, if circumstances were changed, do no better, but a great deal worse, if placed behind the apothecary's counter.

That some prescribing, outside of that done by physicians, is indispensable in the present age, is shown by the vast number of receipts for "cures" of different kinds published in the family newspaper, and by the great number of such clippings carried about in pocket-books.

In a store where counter prescribing is at what is believed to be a minimum, averaging about ten cents per day, or less, it has been noticed that calls for such treatment have gradually fallen off, and at the same time the calls for articles to make domestic cough remedies, tonics, and cholera cures have steadily increased, showing that the public will either be prescribed for over the

* Read before the Adjunct Montgomery County, Pa., Medical Society.

counter or prescribe for themselves. Or, to put it in another form, a large number of persons will not call upon a physician for advice unless they are sick enough to go to bed. And is it to be wondered at? Do not these same people do their own repairing in many other ways; patch their own clothes, darn their own stockings, repair their own harness, do odd jobs of painting, carpenter work, paper-hanging, and a thousand other kinds of mending? It is therefore not surprising that they should occasionally try an odd job of repairing the human form divine.

To show where counter prescribing is done, the following experience of an apotheary who spent eighteen months as head clerk in a store owned by a physician is submitted:

"The proprietor of the store knew nothing about pharmacy. I was given one assistant. The unwritten, but well-understood rule of the store, was to let no patient escape without treatment. Everything was prescribed for, from a slight cold or a cut finger to fever and ague or passing the catheter. The surgical cases were numerous, and frequently serious; gonorrhœa and syphilitic cases frequent; slighter ailments of daily occurrence. In the absence of the proprietor, which was about two-thirds of the time, I was expected to prescribe, and became quite popular with some of the customers, who preferred my medicine to that of the 'other doctor.' One lady asked me to attend her in confinement, and seemed much hurt at my declining to do so. In my absence, the assistant was expected to, and did prescribe for all comers, it being well known that if not supplied with medicine they would go to one of the neighboring stores, which were also owned by physicians, who had the reputation of prescribing for every applicant."

Now, the writer happens to know this physician; and that he holds a diploma as "Doctor of Medicine," and one as "Doctor of Philosophy," from one of the best universities in the country; also that he was recognized and met in consultation by other reputable physicians; also that he was a member of a reputable family. He, therefore, believes it fair to infer that the counter prescribing done in the store of such a physician would not be in excess of that done in other medico-pharmacies. Six other stores, known to the writer, owned by physicians, are probably little else than prescribing shops. The proprietor of one, in which, probably, the least is done, has actually visited the sick in their homes at times when they were too ill to visit him in the store. And yet he claims not to practice medicine. The proprietor of another said of a neighboring practitioner: "What do I care for his boycotting; my counter prescribing is worth more to me in one week than his prescriptions in three months."

It is, therefore, the opinion of your correspondent, that the evil of counter prescribing, so much cried out against, is chiefly confined to physicians, who, for lack of practice, advancing age, or disinclination to continue the practice of a visiting profession, have entered the druggists' ranks for the express purpose of prescribing for the sick who visit them; and that the sin is unjustly placed to the discredit of the regular apothecary, who is usually loth to prescribe, except in emergent cases—while those medical druggists are counter prescribers by choice, and not only give medicine to the patient who is able to visit the store, but send remedies to the bed-ridden patient at home.

Medical Societies.

TRANSACTIONS OF THE PITTSBURGH OBSTETRICAL SOCIETY.

Reported by the Secretary, Frank McDonald, M. D.

Stated meeting, May 6, 1886, J. P. Sterritt, M. D., in the chair.

After the usual order of business, Dr. R. S. Sutton presented the following specimens removed by laparotomy in his private hospital:

1. Pyosalpinx following an attack of pelvic peritonitis in a strumous patient. Right ovary and tube.

2. Enlarged ovaries and tubes from a case of chronic ovaritis, salpingitis, and perito nitis.

3. Enlarged ovary and occluded Fallopian tube from a case of chronic ovaritis, salpingitis, and peritonitis following laceration of cervix uteri in labor. Right ovary and tube.

4. Ovaries and tubes from a case of chronic ovaritis and salpingitis.

5. Ovaries and tubes from a case of peculiar nervous disturbance. Small dermoid cyst, size of chestnut, in one ovary.

6. Fundus uteri and empty cysts the walls of which were thick and vascular, and attached to the uterus.

7. Fundus uteri and both ovaries from a young woman with incurable hysteralgia and horseshoe-formed uterus.

8. Ovaries and tubes from a case of hydro-salpingitis; ovaries enlarged and tubes distended with serum.

9. Enlarged ovaries and tubes from a case case of chronic ovaritis, salpingitis, and pelvic peritonitis.

Of all these nine cases but one patient died, viz., the case No. 8, hydrosalpinx. This patient died of uræmic poisoning a week after operation. Dr. Sutton in his remarks on these cases covered the grounds of recent advances in pelvic surgery so satisfactorily, that at the close he was accorded a unanimous vote of thanks for his remarks, and many congratulations for his success.

Dr. X. O. Werder then read a paper on

Prolapse of the Umbilical Cord.

The child in utero is entirely dependent on the blood of the mother, carried to it through the umbilical cord. Anything interfering with the normal transmission of this vital fluid through this channel between mother and child results very seriously to the life of the latter. It is for this reason that prolapse of the cord is so fatal to the child during birth. According to Scanzoni only 45 per cent., and to Churchhill 47 per cent., of all infants thus born are saved. Death in these cases is produced by compression of the blood-vessels of the funis and interruption of the fœtal circulation, causing asphyxia of the child, as the result of which we find post-mortem hyperæmia of the brain and liver, ecchymosis on the pleuræ and pericardium, etc.

Prolapse of the umbilical cord may be caused by any circumstances which prevent the presenting part accurately fitting the pelvic brim. It is therefore much more common in face, breech, foot, or shoulder than in vertex presentations, but it is in the latter position that the child's life is in greatest danger, because in vertex presentations the head fills the pelvis more completely, and, therefore, subjects the cord to much greater pressure than is the case with other presenting parts. Another very frequent cause is a contracted pelvis, especially contraction of the conjugate diameter of the brain, and other deformities by which the vertex is prevented from readily engaging at the pelvic inlet. Hydramnios, premature escape of amniotic fluid, undue length of the cord, low insertion of placenta, etc., are also frequent causes of prolapsus funis.

The frequency varies greatly according to the statistics of different authors. Churchhill gives 1 : 240; Scanzoni 1 : 254, and other authorities even 1 : 90; the difference probably being due to the fact that the latter have included all positions, while the first speak only of vertex presentations.

The diagnosis of this complication is generally very easy, especially after the rupture of the membranes. Before they are ruptured, however, principally during a pain, when they are very tense, it may be a little difficult; after their relaxation, the presence of a pulsating cord cannot be overlooked or mistaken for anything else.

In the treatment of this complication, it must be our endeavor to *relieve* or to *prevent* compression of the cord. This we achieve either by *reposition* or by *immediate* delivery.

If in a vertex presentation we feel the cord through the membranes, it is our duty to keep them intact as long as possible; we must, therefore, examine very cautiously, especially during a pain, and keep the patient in bed. Schroeder, of Berlin, recommends the introduction into the vagina of an elastic tampon filled with air or water, for the purpose of acting as a counter-pressure against the distended membranes. If we succeed in preventing the rupture of the membranes until the os is fully dilated, we have gained a great deal; because as soon as the head becomes engaged in the pelvis, the cord often slips back; should this not take place, however, we may try with our hand to push it up past the head; or we can push the head to one side as long as it is movable, and thus prevent compression, or place the woman on the side opposite to that on which the prolapse occurs. The most important measure, however, at this stage of labor is, in my opinion, the postural treatment, *i. e.*, the knee-chest position. By placing the patient on her chest and knees, with her hips elevated and shoulders resting on a lower level, the fundus uteri becomes the most depending position, and the cord is apt to slip back by its own weight. After full dilatation of the os, the membranes may be ruptured, and by applying proper external pressure, we may succeed to get the head fully engaged, thereby preventing the funis from slipping down again. Thomas and other authors recommend this method of reposition by gravitation very highly, and it seems to be successful in a large percentage of cases before the liquor amnii has escaped.

The most unfavorable cases are those in which the cord is prolapsed after rupture of the membranes, and before dilatation of the os has taken place. In these cases postural treatment generally fails, and we are obliged to resort to other measures to accomplish reposition. This may now be effected by the hand or by instruments devised for this purpose. We should always try manual reposition first, because it is quicker and less apt

to compress the cord. Only if this fails, be it on account of a small, rigid os, which will not admit a hand or finger, or undue length of the cord, then instrumental interference is indicated. The method practiced in Carl Braun's clinic, in Vienna, is the following: Put the woman on her side or in the knee-chest position, introduce your whole hand, the dorsum of which having been oiled, into the vagina, catch the cord on the points of all five fingers, and push it up gradually and cautiously in the same way it came down, until you have reached the space formed over the chest of the fœtus. Afterwards place the palm of your hand with the fingers over the child's head, put the woman on that side on which the cord does not come down, and withdraw your hand cautiously during a pain.

Quite a number of repositors have been recommended by different authors. They all have no advantage over a common male elastic catheter, which can be improved for this purpose by passing the two ends of a piece string through it, so as to leave a loop emerging from the eye of the catheter. This is passed through the loop of prolapsed cord, and then fixed in the eye of the catheter by means of the stilette. The cord is then pushed up into the uterine cavity by the catheter, and liberated by withdrawing the stilette. A piece of whalebone may also be used as a repositor by cutting a hole into it, then passing a piece of tape through the loop of cord and the ends of it threaded through the eye cut in the whalebone. By tightening the tape the whalebone is held in close apposition to the cord, and the whole is passed as high as possible into the uterine cavity. If desired, this can be left in the uterus. Playfair, Midwifery, p. 304.

Unfortunately, all these methods of reposition fail only too often. The harder we are trying to push the prolapsed cord back, the more it is liable to fall down again; and have we succeeded in replacing one loop, we are chagrined to find that another has prolapsed in a different place. I think, therefore, that we should not waste our time by such uncertain procedures, especially when the life of the child is in danger and when circumstances are favorable for a speedy delivery. The more so, as even after we have succeeded in keeping the funis up in the uterus, the child is not always safe, and unless we keep a careful watch over the fœtal heart, we will be very much surprised to find the child still-born, in spite of all our efforts to save its life. If, therefore, the os is fully dilated, and the head has firmly engaged in the pelvis, we should be ready to apply the forceps without a moment's delay, should the least pause in the expulsive forces occur. If we have not succeeded in replacing the cord, a good plan, before the application of forceps, is to push it back into the region of the promontory of the sacrum, as there it will be least exposed to pressure. Is the head, however, not fully engaged in the brim of the pelvis, or is it still immovable, then the plan to be followed is immediate turning and extraction, provided, of course, the os is sufficiently dilated. Following these rules, we will, under favorable circumstances, almost always be able to deliver a living child, and to remove it from the dangers to which it would necessarily be exposed while in utero. Even if it should be in a state of asphyxia, proper therapeutic measures will generally succeed in restoring it to life.

Following this short resumé of this subject I will give the history of three cases of prolapsus funis observed in my own practice. I could mention a few cases seen during the eight months spent in the obstetrical wards in Vienna, but as I have kept no accurate notes of them, I will not waste your time by a recitation of them.

Case 1 was a primipara attended by me in the first year of my practice. Saw her at 6 a. m. Os hardly the size of a quarter, occipito-ant. pos.; pains good. Returned at 8 a. m. Os now dilated to the size of half dollar, vertex fairly engaged in the pelvic brim, but still immovable. Can feel a pulsating cord through unruptured membranes. Put her in knee-chest position repeatedly, then tried left side, but without success, the cord coming down on the right. Membranes ruptured at 12 m., before the os was much larger than one silver dollar. Loop of cord is now in vagina. Tried manual reposition; sometimes I would succeed in getting one part back, but another would come down; at last tried catheter, but was not more fortunate. Then used hot vaginal douches for the purpose of dilating the os, and gr. xv. doses of chloral hydrate every twenty minutes, as Playfair recommends, giving four doses in all, but with little success. Pulsation in the cord ceased at 2 p. m., delivered child in superior strait with forceps at 7 p. m.

Case 2. February 22, this year, was called to multipara; tenth child. Had been sick for several hours, but pains were not very severe. Os completely dilated; head not engaged yet; left occip.-ant. pos., with head rather to the left of the brim. In examination I unintentionally ruptured the membranes; by external manipulation I tried to bring the head over the inlet, when all at

once one hand and the cord prolapsed on the right side. Replaced hand without much trouble, but had considerable difficulty in getting the cord back, but at last succeeded by manual reposition, the patient on the left side. Manipulated the head into the pelvis. Was at first undecided whether to turn or to let nature take its course and to deliver with forceps, if necessary. But the pelvis being very roomy, the fœtal heart, which was very irregular at first, having become more regular, and the head having become rather firmly engaged now, I decided for the latter. Put patient in forceps position and watched fœtal heart. But shortly one severe pain carried the child through the whole pelvic canal. Though somewhat asphyxiated, I had not much trouble in resuscitating it.

Case 3. Multipara; tenth child, of which five were born dead. Had never attended her before, but learned that shoulder and other abnormal presentations had always been the cause of death. At 8 p. m., May 18, of last year, she had one severe pain, which ruptured the membranes and brought down a large loop of cord. She went to bed immediately and kept very quiet. I did not arrive until 11 p. m., three hours later, and found over two feet of funis in bed, still pulsating and knotted in one place. Os completely dilated; head movable above pelvic brim. Has had very little pain since taking the bed. I at once decided to perform version. But by the time I had placed the patient in a suitable position for this operation, pulsations in the cord had ceased; nevertheless, I seized one foot, brought it down and extracted the child immediately, the whole operation probably not lasting one minute. The child was completely asphyxiated, but the heart was still slightly beating. It was at least ten minutes before the child performed the first act of respiration, which was followed by another one minute later, and so on; but respiration did not become regular until forty-five minutes after birth. In the meantime I kept up artificial respiration, practicing, especially, Schulze's method. I am pleased to say that the child to-day is in perfect health; by less energetic treatment its life would certainly have been sacrificed. As I stated before, the cord was knotted and measured thirty-eight inches.

Dr. Werdes' paper was discussed by Drs. Kearns, Bloomburg, Sterritt, Green, Duff, and Sutton, and referred to the Secretary for publication.

There being no further business before the Society, meeting adjourned.

NEW YORK NEUROLOGICAL SOCIETY.

Stated meeting, June 1, 1886. The President, Charles L. Dana, M. D., in the chair.

Trigger-Finger (Doigt a Ressort).

Dr. George W. Jacoby read a paper on this affection, which, he said, was, strictly speaking, one of a surgical and not of a neurological nature; that is, if its pathology, as at present accepted, was correct. These cases, however, when encountered by the general practitioner were liable to be referred to the neurologist; hence the importance of being able to diagnosticate the condition. Doigt à ressort was the name given by Nélaton to a peculiar inhibition of motion in fingers otherwise normal. Flexion completed by force, the movement resembled the closure or opening of the blade of a pocket-knife. Sometimes only extension was interfered with. As a rule, muscular effort alone was sufficient to overcome the obstacle. Generally, the entire motion was painful, particularly at the time of the snap. The patient usually located the pain in the interphalangeal joint, but a careful examination would show that it was at the metacarpo-phalangeal articulation. Externally, the finger presented nothing abnormal, but pressure over the last-mentioned joint almost always produced pain, the painful point being usually confined to a small place upon the volar surface of the flexor tendon. In all cases except those of Busch and his own, a hard, lentil-sized body, which was particularly painful to pressure, was found attached to the tendon about two centimetres above the digito-palmar fold. All authors laid stress upon the presence of this body, as it was, according to all theories of the mechanics of this phenomenon, essential to its production. In Dr. Jacoby's first case he did not remember to have found any nodosity, but as he did not pay particular attention to it, it may have been overlooked. In his second case, however, knowing of the cases of Busch and of Marcano's criticism on them, he made a very careful examination, and could say positively that there was no nodosity or abnormality of any kind discoverable. He saw his first case in 1881, but did not make a diagnosis. The patient was a female servant who almost continually had her hands in water. She had had vague rheumatic pains for years, but had never had an attack of acute articular rheumatism. About six months prior to her visit to Dr. Jacoby she began to have a peculiar tingling sensation in the ring-finger of the left hand, with shooting pain upward

in the arm; she also complained of weakness of the finger and difficulty in flexing it. There was, however, no distinct ressort until two months before he saw her; then she was unable one morning to close the finger, and in attempting to aid herself with the other hand the finger suddenly snapped shut. Dr. Jacoby saw her only once.

The second case was that of a clerk aged 28, whom he saw in November last. The middle finger of the right hand was affected. There was no apparent cause; the patient had never had rheumatism, nor sustained an injury of the finger. The phenomenon came on very suddenly while he was engaged in writing, and was very much fatigued. He made his own diagnosis of writer's cramp, and a physician whom he consulted coincided with this diagnosis. Upon examination, Dr. Jacoby found the peculiar snap to be well marked, and the patient was unable either to fully extend or flex the finger without the aid of the other hand. Both flexion and extension caused severe pain. Pressure over the metacarpo-phalangeal joint was painful. Repeated and careful examinations failed to reveal the presence of any nodosity or irregularity whatsoever. The treatment consisted in the application of the galvanic current, but after a few sittings the patient disappeared from under observation.

The affection had been described and cases published successively by Notta and Nelaton, by Fenerly, Arrachart, Busch, Annandale, Dumarest, Hahn, Menzel, Fieber, Vogt, Blum, Felicki, Herraez, Leisrink, Marcano, and Largeau. The only reference to it which Dr. Jacoby had been enabled to find in any English or American periodical was a translation of Menzel's article, published in the *Boston Medical and Surgical Journal*, 1874, and the description of a case by Annandale, which, however, he evidently did not recognize as a case of doigt à ressort. Dr. Jacoby gave tables of thirty-three cases by different authors. Twenty-one cases were in women and only ten in men, in two the sex not being specified. All the cases were in adults excepting two. Occupation seemed not to have any influence in the production of the malady. The fingers affected were the thumb 16 times, the ring finger 15 times, the middle 6, the small finger twice, and the index finger only once. In five cases more than one finger was affected. The etiology must in the majority of cases be sought in rheumatism; next in traumatism. In some cases no direct cause could be found. The diagnosis was easy. The prognosis was generally fair, as the symptoms usually disappeared after several weeks of appropriate treatment.

Dr. E. C. Seguin said he had never seen a case of true doigt à ressort. He had seen two cases which resembled this condition, but which were of an entirely different nature in their etiology. They verified the author's statement that such patients were likely to be sent to a neurologist, and he should therefore prepare himself to make a diagnosis. In one of the two cases to which he referred, the patient was unable voluntarily to flex the terminal phalanx of the thumb, and if it were forcibly flexed it would go back with a jerk. There had been section of the long flexor of the thumb.

Dr. M. A. Starr, who had also seen the second case referred to by Dr. Seguin, said the difficulty, which was due to section of a tendon, had been mistaken for paralysis, but Dr. Seguin corrected the error in diagnosis. A surgeon had sent another patient to Dr. Starr within a week who at his work was accustomed to make a firm pressure with his hand, and suddenly he experienced difficulty in flexing his fingers, being entirely unable to flex the little finger. The faradic current caused flexion of all the fingers but the little one. He sent the patient to a competent surgeon, who made the diagnosis of fracture of the long flexor tendon of the little finger.

Dr. Willy Meyer had seen two cases of doigt à ressort in Europe. One came to the surgical clinic at Bonn while he was assistant. In both patients the middle finger was affected. One patient was a man, the other a woman. In the case of the man a very thorough examination was made, but no apparent pathological change was present. He was able to use his hand, but with some inconvenience. He wore a splint four or five weeks, which left the finger a little stiff, but this was overcome by prolonged warm baths and passive motion. The woman had complained about two months of pain along the flexor tendon from the middle of the palm of the hand to the tip of the finger, the pain having grown steadily worse. A small painful nodosity was felt just below the metacarpo-phalangeal joint. As there was no doubt that this nodosity was the cause of the affection, they advised its removal, but the patient refused. There were two interesting cases of trigger-finger published in the *Centralblatt für Chirurgie*, 1884, No. 16.

Dr. Meyer thought there was always a mechanical cause of the disease, for even in those cases in which no peri-articular pathological symptom was observable, there might be something wrong within the articulation.

As to treatment, were there no apparent cause for the difficulty, he would use the plaster-of-Paris splint, massage, prolonged hand-bath, passive motion, and perhaps electricity would be advisable. If a nodosity were found it should be removed.

Gilles de la Tourette's Disease.

By C. L. Dana, M. D., and W. P. Wilkin, M. D.

Dr. Wilkin read the paper, in which he said that Gilles de la Tourette's disease was an affection characterized by incoördinate movements (tics convulsives) and by echolalia (automatic echo-speech) and copsolalia (or automatic obscene speech).

The description of the disease by Beard, O'Brien, Hammond, and Tourette received attention; and reference was made to the unity of Latah, Myachit, the Jumpers, and Tourette's cases of tic convulsive.

The disease, the speaker said, begins almost without exception by attacks of motor incoördination, affecting, generally, the head, face, and upper extremities first, then involving the whole body.

After remaining perfectly quiet, the patient suddenly makes frightful grimaces, blinks the eyes, snaps the jaws, raises the shoulders, etc., etc.; if the lower extremities are affected the patient stamps his foot, raises himself, and jumps as he walks.

After having suffered from attacks of motor incoördination for a time, the patient will with the attacks utter inarticulate cries, or he may begin to repeat or echo the words he overhears (echolalia). All this is done automatically and suddenly, and usually with the accompaniment of grimaces and muscular contortions.

In the speaker's case, the attacks of explosive obscenity, or copsolalia, had been more prominent than the incoördinate movements. The patient, a boy of twelve years, of neurotic history, when sitting quiet, would suddenly and involuntarily burst out into expressions of the most profane and obscene character, repeating them rapidly for a few moments and then stopping.

A surprise or sudden noise of any kind tended to produce an outburst, just as surprises in other cases brought out jumping or incoördinate movements. The condition of echolalia in the case, although less prominent than the copsolalia, was nevertheless well marked. The patient also seemed impelled to tell those things which he most wished to conceal.

The motor disturbances were more marked after the patient through some restraint had to repress his outbursts of obscenity. The movements and expressions could generally be voluntarily controlled for a while, but only to burst forth again with greater violence.

The sudden interjections by the patient of obscene words and expressions was regarded by Tourette as pathognomonic of this affection.

The disease is a chronic one, beginning insidiously and lasting for years, sometimes for a long lifetime.

None of Tourette's cases were cured, though some were greatly ameliorated. The diagnosis of the disease is not difficult. From chorea it is distinguished by the suddenness and larger range of the involuntary movements, and by the fact that a muscular explosion is followed and preceded by complete rest. The symptoms are those of a convulsive tic. Echolalia and copsolalia may form part of the symptoms of insanity; and copsolalia has been observed in aphasia. It is easy to differentiate those conditions.

As to the pathology, from the long continuance of the disease an organic lesion can be excluded; and from the general history it is apparent that it belongs to the neuro-degenerative disorders.

In the treatment one measure had proved of marked benefit, namely, isolation. Tonics, bromides, arsenic, and electro-therapy had caused some amelioration.

The President remarked regarding the case that the patient had improved very much under treatment. It was one of the cases in which moral agencies had the power of suppressing the symptoms for a time. The audience had probably observed that while sitting quietly the patient had exhibited a peculiar kind of cough, which was about the only thing noticeable.

Dr. Graeme M. Hammond asked whether the boy was cruel.

The President replied, not to his knowledge. The only bad trait which the boy had manifested was the disposition to lie.

Dr. Julius Runisch thought it probable the disease as described by Hammond was the same as that prevailing in Kamtchatka. Persons suffering from acute or chronic belladonna poisoning exhibited this jumping tendency. A further interesting fact was the similarity between the symptoms manifested by this class of patients and those of certain persons sensitive to tickling. Some persons suffering from mental weakness or a mild form of insanity were disposed to pronounce very obscene words, to manifest twitchings of the face and other involuntary

movements, which they sometimes took pleasure in observing in the mirror. It hardly seemed to him that the description of the case presented to-night accorded with that given by Beard, and of those in Siberia and similar ones in Java.

Dr. E. C. Seguin thought it might be questioned whether the case presented was like Tourette's on the grounds expressed by the author, namely, the different mode of development, the order of development, and the fact that this patient had a defective mind, whereas Tourette's patients had a normal mind. Still, this might be a case in which there was simply an inverse order in the development of the phenomena. He would like to enter a protest against the nomenclature of the disease, especially as it presented no definite clinical history. In some of Tourette's cases there was absence of echolalia as well as copsolalia. He preferred Charcot's definition, that of tic convulsive, which might include quite a variety of jerking affections; or another term, embracing all possible varieties of these cases might be employed, as abnormal chorea. An interesting, but almost forgotten French monograph of about 150 pages, on these jerking affections, was published at Strassburg in 1850. An interesting case had been reported by a distinguished surgeon of New York.

Dr. M. A. Starr referred to a case related by Dr. Mills, of Philadelphia, in which a tumor involved the second frontal lobe on the left side and pressed upon the third. One of the prominent symptoms was the tendency on the part of the patient to use profane and obscene expressions, apparently without any power to control it. The case suggested the question, Why, since irritation of the central convolutions would produce involuntary motion, irritation of the third frontal convolution should not produce involuntary speech?

The President was perfectly aware that the case was one difficult to classify, but he felt positive if there was such a disease as that pictured by Tourette, this patient had it. In one journal which he consulted the name Gilles de la Tourette was given it by Charcot, and he was much surprised to hear Dr. Seguin say that he did not approve of the name. However, he agreed with Dr. Seguin that there were objections to the name. He could not understand how some of the gentlemen arrived at the opinion that the condition in this case was due to insanity; for the boy, although there seemed to be some defect in his mental nature, did not manifest any symptoms of insanity.

Notes of a Case of Involuntary Muscular Movements Accompanied by Coprolalia.

Dr. T. C. Railton thus writes in the *Med. Chronicle* for April:

The case I have to record is that of a gentleman, now about forty years of age, who for a number of years has been afflicted by a very unusual and distressing nervous affection. He is of good family and is possessed of ample means. His education was received at a public school and at Oxford, and for some years he was an officer in the army. By his social status and his intelligence he is fitted in every way to take a prominent position, were he not debarred in a great measure by his complaint from the society of his equals.

I am given to understand that the disease in question first made its appearance when he was about seven years old, and that it was then ascribed to the effects af a fall. My personal knowledge of him extends back for the last eleven years, and I shall give in my description only those symptoms which have I myself observed. I am unable to give particulars about his family history, but I believe that one of his father's brothers was insane. When I first knew him I noticed that he was subject to occasional sudden involuntary movements, mainly affecting the right upper extremity, but sometimes the leg, either movement being nearly always combined with a contortion of the face or a jerk of the head, or both together. These movements would be repeated two or three times, and would usually be accompanied by a short, inarticulate cry, corresponding in rhythm with the movements. For example, if he were at table when seized with one of his spasmodic movements, he would tap the side of his plate several times in succession with his knife, or even tap his forehead with it, with his face a little distorted and his eyes turned upwards. The inarticulate cry would be uttered with each tap. He did not lose

consciousness nor change color, and when the movements were over, he would appear perfectly well and continue to converse as if nothing had occurred. If it happened to be one of his good days, the movement and sound might not recur for two or three hours; if, on the contrary, it was a bad day, they would be repeated frequently. The same phenomenon would occur sometimes when he was writing a letter, and the paper would then be dotted with specks of ink in the places into which he had dug his pen. When the lower extremity was attacked, he often kicked the toe of his boot vigorously into the ground, and usually tapped his forehead with his right hand and turned up his eyes at the same time. On other occasions he would perform the following series of movements: first, holding out his right hand, he supinated and pronated the forearm two or three times, digging his elbow into his side with each supination; then he raised his right knee and patted it several times; and lastly, he struck his nose, forehead or the top of his head with his hand, opening his mouth and turning up his eyes, and accompanying each tap with the inarticulate cry. The movements seemed to increase in this series, and the blows to the face or head were tolerably hard ones. At this period the cry was perfectly inarticulate: sometimes it was almost a squeak, sometimes like ahem, as in clearing the throat. It never occurred except at the time of one of his involuntary movements. The movements varied very much, but a particular set seemed to predominate for a certain time, to give way in turn to another series. For some time he was in the habit of making a peculiar noise with his tongue and lips, like the sound of spitting out some small thing from between the lips. Probably the disease had slowly reached this stage in the course of over twenty years, and it remained much the same for the succeeding three years of my acquaintance with him, sometimes seeming worse, the movements being larger, more perceptible, and more frequent in their occurrence; sometimes better, when they amounted only to a slight occasional jerk of the hand, or a tapping of the forehead.

In 1882 I observed that a new phenomenon had supervened, rendering his complaint much more seriously inconvenient. Instead of the inarticulate cry, the movements were accompanied at times by a muffled sound, the purport of which could not be distinguished when it was first heard, but which became resolvable by its repetition into words never used in polite society. He would be painfully conscious of the effect upon his audience of the word or words he used, and would endeavor to turn off the obnoxious sound by continuing it either into a humming of a bar or two of music, or as a strenuous cough. But sometimes the words were audible with startling distinctness, and I have repeatedly witnessed him nodding his head several times in succession, with his mouth open, and his eyes turned upwards, tapping his forehead with his hand in unison with his nods, each nod being accompanied by an improper or obscene word. The words uttered were usually "bloody hell," but sometimes he used words of a more filthy description, which it is needless to further particularize. Such attacks formed a most painful contrast to his surroundings and to his manners, which were those of a cultivated gentleman, who, in conversation, never made use of obscene or improper language. M. de la Tourette, who has collected nine cases of this disease, has applied the term "coprolalia" to this symptom, from κοπρος=filth, λαλεω=to talk; and he considers that it is pathognomonic of the disease. In the case I am reporting, the improper word was sometimes interpolated in a sentence in a very disastrous fashion, when an involuntary movement happened to occur while the patient was speaking. Thus I have heard him inform a lady that it was "a bloody fine day," and immediately try to divert attention from the word by repeating "*very* fine," "*very* fine," with an emphasis upon the adverb. He would often endeavor to smother the sound, and by great efforts he could succeed for a time in checking what was an almost irresistible impulse, but this was not always possible. If he had occasion to speak in public, no trace of this complaint showed itself. There was no disorder of sensation, his health was always excellent, and his intelligence and general knowledge were above the average. In fact, the disease did not appear to have affected him in any way, either mentally or physically. I last saw him in 1883, and perceived no change of any moment; perhaps the movements were slighter as a rule, but the coprolalia was observed as frequently as before. It is quite possible that the disease may continue as it is now, without the supervention of any additional symptoms; one of de la Tourette's cases suffered from it in this form for about 60 years; but it is also possible that a further development may take place. He considers the disease to be incurable, for while nervous sedatives seem to have an influence, yet as the disease naturally presents periods of ameli-

oration, it is difficult to verify this observation.

Specific Disease of the Brain and Spinal Cord; Symptoms of Locomotor Ataxy.

Dr. Albert Leahy thus writes in the *Brit. Med. Jour.*, June 12:

Mr. Hutchinson's lectures on syphilis, recently published in the *British Medical Journal*, together with the doubt that has been expressed as to the occurrence of ataxy, having syphilis for a cause, may render the following case interesting:

G. W., an officer in the army, aged 46, of temperate habits and nervous disposition, began to complain of debility early in 1885. Twenty years previously, he contracted a sore, which was cured in a fortnight, and, as far as he could remember, was not followed by secondary symptoms. In April, 1885, he complained of weakness in the legs, exhaustion after slight exercise, loss of appetite, and feverishness. This weakness of the legs increased, and he was sent to the hills. About the middle of June, he came under my observation. He complained of lightning pains in his lower limbs, and tingling sensations, "as of pins and needles," in both arms. Both his arms and legs were slightly paretic; and, when he stood up, there was some trembling of the legs and thighs. His gait was typically ataxic, and he described the sensation of contact of the soles of his feet with the ground as being "distant," and as though they were covered with felt. He had external strabismus on the right side, with dilatation of the pupil, and absence of power of accommodation. There was paralysis of the soft palate, causing regurgitation of food into the posterior nares; and each tonsil was the seat of a circular depressed ulcer, with a ragged edge and yellowish base. The patellar and ankle reflexes were absent, and he could not stand with his feet together and his eyes closed. Both eyes were examined with the ophthalmoscope, but nothing abnormal was discovered. On the skin of the forehead was a coppery papular eruption. The inguinal glands were enlarged, but there were no scars on the penis. The paralytic symptoms became rapidly worse; in three weeks, he had completely lost motor power in his lower limbs, and had much difficulty in moving his arms. The muscles of the limbs wasted rapidly, but retained their electric excitability. He had cough, with mucopurulent expectoration, and there were slight dullness and harsh breathing at the left apex. The daily temperature was normal, and there was no albumen in the urine. Iodide of potassium, in ten-grain doses four times a day, with drachm doses of the solution of perchloride of mercury, were first given towards the end of July, and were persevered with for over two months. The patient gradually improved, regaining the power of motion in his lower limbs, and losing the strabismus. During the third week in August, he became extremely irritable, and, on one occasion, violent; the twitchings and startings of his legs also caused him trouble; and the dose of iodide of potassium was increased to 15 grains. The eruption on his face gradually diminished. The improvement in the paralysis gradually increased; and, by the end of September, the patient was able to move about his room, and to take short walks, with assistance. The medicines were stopped during the first week in October, but had to be resumed, as psoriasis of the palm of his right hand (with which he used his walking-stick) appeared. The improvement in his case, up to the time of his leaving India (November, 1885), was permanent.

Whether the ataxic symptoms depended upon the syphilitic poison, or whether they were merely coincident, is open to discussion; but the fact remains unaltered that, as the paralytic symptoms disappeared, the peculiar gait, the swaying to-and-fro when the eyes were closed, and loss of the reflexes, were no longer observable.

Rupture of the Female Urethra during the First Coitus; Imperforate Hymen.

At a recent meeting of the Cronstadt Marine Medical Society, Dr. N. A. Esipoff communicated (*Meditz Obozr.*, fasc. i., 1886, p. 47,) a case of the following nature: A newly-married female, aged 19, who had never menstruated, but every three weeks suffered from menstrual molimina, during the first coitus suddenly felt acute burning pain in the vulva, which was followed by very profuse hemorrhage, both of the parties being in an inebriated state at the time. When first seen, five hours later, the patient was found to be anæmic, the source of the still-continuing hemorrhage being a laceration of the urethra about two centimetres long, running from the edge upwards to the bladder. A fluctuating tumor of the size of a hen's egg was bulging from the vaginal orifice. It was covered by the normal skin, with distinct veins. A finger introduced into the rectum revealed a fluctuating cyst occupying the whole lesser pelvis. The womb was greatly distended, its fundus being felt a finger's breadth above the navel.

After arresting the bleeding by cold water douche, the author closed the wound with five sutures of reindeer tendon, and introduced Nélaton's catheter *à demeure.* Three days later the wound was found healed by the first intention, no trace of sutures being left. On the fourth day (after the accident) a large-sized trocar was thrust into the distended hymen to remove about 2,000 cubic centimetres of inspissated, tar-like, inoffensive menstrual blood. Then, having washed out the cavity with a sublimate solution, the author enlarged the puncture with a bistoury. On exemination, neither vaginal roof nor vaginal portion of the womb were found, the uterus and vagina representing one cavity, with a slightly prominent ring at the level corresponding to the internal uterine os. A week later, the womb assumed its normal size; the cervix was formed already, but was still somewhat short and flabby, the external os being patent, its edges star-like and knotty. Dr. Esipoff mentions also a case of hæmatometra in consequence of congenital atresia of the hymen, in a strong, well-nourished hotel servant, aged 17, with menstrual molimina of a year's standing, and with the fundus uteri felt three fingers' breadth above the pubes. No discomfort whatever was ever felt by the patient. The author performed the same operation as in the former case. As in the first case, the womb and vagina were found to be transformed into a single cavity, the cervix being almost tracelessly leveled in consequence of prolonged and considerable distension. Dr. Esipoff lays stress on that point, for Professor Schroeder, in his hand-book, states that in cases of hymeneal atresia only hæmatocolpos is present, while true hæmatometra occurs only in cases of atresia of the external os uteri.

The Microbe of Rabies.

Dr. G. F. Dowdeswell thus writes in the *Lancet,* June 12:

In view of the great interest now taken in this subject in consequence of the brilliant investigations of Pasteur, I think it desirable to take an early opportunity of stating that I have found the microbe which appears clearly to constitute the virus of this disease. It is a micrococcus, not very minute, and of the usual form. It stains, however, with some difficulty; and this accounts for its having hitherto escaped observation. In the cases of dogs which I have as yet examined, its principal seat is evidently the central canal of the spinal cord and medulla oblongata; thence it pervades the other tissues of the central nervous system, occurring (sometimes in vast masses) around the walls of the blood vessels, and in some cases within the vessels amongst the red blood-corpuscles. In the cortex of the hemispheres I have found it, but in very small numbers, and, so far, only in the peri-vascular and peri-cellular lymph spaces. In the cerebellum I have not found it at all, neither have I as yet succeeded in finding it in the salivary glands. I shall shortly publish the methods by which it may be stained with certainty. I must, however, state that it does not stain by hæmatoxylin, either with or without a mordant, as asserted by some. I have repeated their methods carefully. Neither does it occur within the nerve fibres, as stated; and, lastly, it is fully three times the dimensions which they give. I may add that it does not occur in the same situation, treated by the same methods, in normal animals. In the one case of a rabid dog, which I had examined to control my previous observations, the tissues were placed in alcohol so shortly after death as to preclude the possibility of the occurrence of septic organisms. In addition to which, all saprophytes, as far as yet observed, stain very readily with the usual aniline dyes, which this microbe does not. I must point out, in justice to the genius of Pasteur, that these observations on the occurrence of the microbe go far to confirm his statement of the seat of the virus; it may further afford a means of diagnosis in any doubtful case.

Rupture of the Uterus, Followed by Laparotomy.

At a meeting of the Gynæcological and Obstetrical Society of Paris, Dr. Doléris produced the uterus of a woman where rupture of the uterus had occurred during labor and the child had escaped into the peritoneal cavity. Delivery was, however, effected *per vias naturales;* but, two days later, the patient's condition having become very serious, he performed laparotomy under strict antiseptic precautions. The wound in the uterus, as well as the right broad ligament, which was torn, were sutured, and the peritoneal cavity carefully cleansed. The patient, however, did not rally from the shock of the operation, and died a few hours later. At the necropsy, the rent was found to extend from the right side of the cervix towards the right angle of the uterus, and thence inclined to the left. The right broad ligament was torn completely through, and the left was damaged to a less extent. Dr. Doléris expressed the opinion that immediate recourse to laparotomy would have been preferable.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The official report of the memorial meeting of the New York County Medical Association in honor of the late Dr. Austin Flint is published in pamphlet form in appropriate style.

——In a short reprint, Dr. John M. Keating, of Philadelphia, makes some timely suggestions for the preparation of milk for infants.

——Mr. George S. Davis, of Detroit, Mich., forwards an announcement of his "Physician's Leisure Library," which embraces twelve monographs for the very reasonable price of $2.50.

——A remote effect of peripheral irritation is illustrated by Dr. D. B. D. Beaver, of Reading, Pa., in the description of a case of retinal hyperesthesia due to masturbation and its consequences.

——Mr. J. L. Milton, an eminent London surgeon, in a brief pamphlet before us discusses with much erudition the historical side of the question as to the unity or duality of syphilis, showing that the duality was noted in the earliest outbreaks of true syphilis.

——Dr. C. Labus, of Milan, Italy, forwards a reprint describing the removal of a papilloma from the trachea.

BOOK NOTICES.

Transactions of the Vermont Medical Society for the year 1885. Pp. 105. Montpelier, Vt. 1886.

We find in this volume the usual minutes of proceedings, reports of delegates, necrological notices, and a variety of original contributions. Dr. W. T. Smith speaks of lesions of the cerebral hemispheres; Dr. C. S. Caverly, of the causes of infectious diseases; Dr. C. E. Chandler, of the Kocher method of reducing dislocations of the humerus; Dr. L. M. Greene, of fracture of the vertebræ; and others.

Esoteric Christianity and Mental Therapeutics. By W. F. Evans. Cloth, 8vo., pp. 174. Boston, H. H. Carter & Karrick, 1886.

That there are readers for works of this kind is no favorable sign of the times. It is a treatise on the faith-cure, seeking to assimilate it to a form of Christianity. The pages are full of myticism, muddy theology, and intentional obscurities. Such a book is a good one *not* to spend time upon.

Manual of Differential Medical Diagnosis. By Condect W. Cutler, M. D. 12mo., pp. 161. New York, G. P. Putnam's Sons, 1886.

The scheme which is pursued by the author of this little treatise is to arrange in parallel columns the characteristic signs of diseases which are closely allied, and thus bring out their differences. He deserves credit for his careful collation, but this method, when exclusively depended upon, as in the present volume, passes beyond the limits of its utility, and is sure to be an unsafe guide. It is only serviceable when combined with actual description.

Illustration of Unconscious Memory in Disease, Including a Theory of Alteratives. By Charles Creighton, M. D. Cloth, 8vo., pp. 212. J. H. Vail & Co., New York city.

That unconscious memory exercises a most potent influence on the destiny of the individual and the species, cannot be denied. Everything, in fact, that is called by writers "heredity," "atavism," or "filiation," may be embraced under this term, "unconscious memory," if we choose to stretch it far enough. The author of this volume is willing to stretch it to any extent, and hence evolves a most all-embracing theory of the causation of disease. Undoubtedly he makes some excellent points, and we commend his book as one highly suggestive, and worth attentive perusal; but all will smile when he carries his hypothesis so far as to explain yellow fever and Texas fever in cattle as a sort of vicarious disease, originated not by exposure and hardships in those who suffer them, but in those who do *not* suffer these extremities!

Traite Elementaire d' Anatomie Medicale du System Nerveux. Par. Ch. Féré. Pp. 493. A. Delahaye, Paris, 1886.

The anatomy of the nervous system is fully set forth in this treatise, and with the lucidity which characterizes the writings of French scientists. The scope of the volume includes not only the descriptive and topographical anatomy of the nerves, but pathological conditions, and the more important medical applications as well. There are a number of illustrations, chiefly wood-cuts of moderate excellence, and the type is clear.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

ERYSIPELAS AND PUERPERAL FEVER.

There still are many physicians who contend that erysipelas and puerperal fever really are one and the same disease. Fehlersen has recently demonstrated that erysipelas is caused by special cocci, utterly different from the germs met with in puerperal fever.

Dr. Gusserow now publishes some cases in the *Arch. f. Gyn.* xxv., p. 169, where he proves, from a clinical point of view, the impossibility of both being produced by the same poison. He first mentions two cases of erysipelas occurring during pregnancy. In the first case, four days before delivery, erysipelas of the face began, and continued for four days after it. Childbed normal. In the second case the woman contracted erysipelas in the eighth month. It attacked only the lower extremities. In consequence of the extremely high fever the child died the thirteenth day; the sixteenth, delivery, soon after exitus letalis of the mother. Post-mortem showed uterus and appendages perfectly normal.

As further evidence, G. mentions a case where the mother, four days after delivery, was seized with erysipelas faciei. This ran a normal course and did not influence in the least the progress of the puerperium. In another case erysipelas attacked the left mamma eight days post-partum and seven days later exitus. Autopsy revealed a very grave form of erysipelas, but uterus and appendages normal.

Next, G. publishes nine cases of erysipelas, where it set in after septic phenomena had already existed. In all these cases there appears no causal connection; the septic symptoms had lasted in some eleven days ere the skin commenced to suffer from erysipelas, and the latter disease progressed and ran its course without influencing in any way whatever the septic signs. The autopsies in the fatal cases demonstrated the existence of grave septicæmia, and proved the fact that the erysipelatous inflammations had not been phlegmons, but true erysipelas. To finally conclude the dispute, G. took some of the cocci of erysipelas, and introduced them into the peritoneal cavity of a gravid rabbit. No morbid symptoms of any kind made their appearance.

These investigations are of importance in so far as a physician, because attending a case of erysipelas, need not hesitate to guide a woman safely through childbed, though it will always be safer to take care at least of thorough disinfection of hands, instruments, etc., under such circumstances, for as one of the above cases above referred to again

proves, erysipelas is by no means always a mild complaint, but often enough a fatal one. In our country, however, the latter disease does not seem to be so often attended with danger to life as in the old countries, where the large laboring population does not live under the same favorable hygienic conditions as happily is the case with us.

By all means the researches above mentioned demonstrate that a physician, when finding a woman, whom he delivered of a child, suffering from puerperal fever, need not feel that he has been the cause of this dangerous malady, because he had attended a case of erysipelas at the same time. Such a knowledge would greatly ease the conscience of any conscientious physician.

PASTEUR'S INSTITUTE.

At the meeting of the Paris Academy of Sciences, March 8, this year, a committee was appointed to consider the possibility of erecting an "International Institute for the Prevention of Hydrophobia." Pasteur remarked at the time that in case the Academy should endorse the erection of such an institute, subscription lists should be opened in all civilized countries, that a sufficient amount be procured to enable the commission in charge of the institute to allow free passage to and fro for all persons bitten by rabid animals desiring to be admitted into the institute, but too poor to pay the traveling expenses, as only thus a full benefit would accrue from the erection of such a hospital.

Secretary of the Interior von Freycinet, who also was present, promised the assistance of the government, and at the earnest solicitation of the President of the Academy, consented to become a member of the committee.

The latter has handed in its report, which it concluded in two special meetings. Vulpian, as chairman of the committee, presented the report to the Academy and the latter accepted it as follows:

§ 1. In Paris an institute is to be erected for the treatment of hydrophobia after injury by a rabid animal, its name to be "Institute Pasteur."

§ 2. Into this Institute Frenchmen and foreigners are received who have been bitten by rabid dogs or by other animals suffering from hydrophobia.

§ 3. In France, as well as in other countries, a public subscription is to be opened to obtain the means for the erection of the Institute.

§ 4. The means procured by this subscription are placed in charge of a commission to consist of (now follow the names of the most celebrated scientists and the most prominent men of France, of whom we will name the following: Admiral Jurien de la Graviere, President of the Academy of Sciences; Vulpian, Marcy, Paul Bert, Charcot, de Freycinet, Jules Simon, Magnin, Governor of the Bank of France, A. de Rothschild of the Crédit Foncier, Be Clard, Dean of the Medical Faculty, and the faithful, untiring colaborer of Pasteur, Prof. Graucher, is also not wanting).

§ 5. Subscriptions are received by the Bank of France and its branches, the Crédit Foncier and its branches, all internal revenue collectors, etc.

The names of the subscribers will be published in the *Journal* of the Academy. Thus an enterprise is assured, upon which we all can only look with the utmost sympathy, though the final decision about the effect of Pasteur's method must still be reserved.

TO DETECT THE SEX OF THE FŒTUS BEFORE DELIVERY.

Dr. Juan Bidart, of Santiago, Chili, has recently made a long series of observations to determine whether it might be possible to detect the sex of the fœtus by the number of the beats of the pulse.

Towards the end of pregnancy B. counted in 100 cases the fœtal frequency of the pulse, sometimes once, sometimes oftener, according to circumstances. He arrived at the following conclusions:

1. There exists a definite relation between the sex of the fœtus and the frequency of its pulse, and the figures 135 and 145 form the limits to determine the question.

2. Contractions of the heart less frequent than 135 indicate a boy, while more than 135 or 145 give evidence of a girl.

3. To determine the point, it is necessary to count the number of beats oftener before rupture of the bag of waters, to become acquainted with the rhythm of the heart, and any possible irregularities.

4. Under such circumstances the sex may be predicted with certainty 92 out of 100 times.

5. The knowledge of the facts may be of great importance when determining the advisability of premature delivery.

RAPHANIA.

Raphania is the technical name for that class of poisoning produced by strawberries,

ergot, and especially the black radish. Dr. J. Andree reports the case of a man, æt. 51, and that of his son, æt. 25, who both after the eating of horse-radish suffered from intense pains in the epigastrium and in the extremities (*Centrlbl. f. d. Med. Wiss.*,4,'86). These pains were so severe that the patients rolled around on the floor. About 1½ drachms of resorcin, and, in the case of the father, half an hour later a second dose of about 50 grains induced vomiting and diarrhœa, and at once brought about a great amelioration in the symptoms.

Dr. A. also made use of the same remedy in case of ergotism, and he strongly recommends the drug in all similar instances.

Notes and Comments.

Tabetic Contracture of the Old.

E. Demange was the first to draw our attention to a peculiar form of contracture, which attacks only the aged when suffering from arterio sclerosis in a high degree, and which is characterized mainly by a progressive contraction, which gradually seizes the joints of the extremities.

In a recent article in the *Revue de Méd.*, 1886, No. 7, D. reports several cases of this disease and tries to show the distinguishing points between his diffuse sclerosis," due to vascular disturbances, and the common lateral sclerosis. While in the latter disease the lateral columns alone suffer in his "diffuse sclerosis," though the same paths also are mainly affected, the other parts of the spinal cord also become the seat of the same morbid changes, but in an irregular manner.

From the nature of the pathological lesion, as described by D., we infer that the minute alterations also differ in the two diseases. In lateral sclerosis we have to do with a real sclerotic process attacking the white matter of the lateral columns, while in the diffuse vascular sclerosis of the aged the arteries are seized by the sclerotic process, and according to the portions of the cord thus deprived of their usual supply of arterial blood, we find atrophy of the white matter in irregular patches, but usually extending over a transverse part of the medulla.

This atrophy macroscopically greatly resembles true sclerosis, but the microscopical examination shows in the one case a cicatricial contraction of the interstitial tissue and consequent wasting of the compressed white matter, and in the other an atrophic process, attacking alike all the structures receiving their arterial blood from the same sclerotic vessel.

The Effect of Some Poisons on Ascarides.

To determine the effect of certain drugs on intestinal worms, Dr. W. V. Schroeder has instituted a series of experiments and published their results in the *Arch. f. Exp. Path. u. Pharm.*, xix., p. 290. He used the ascaris lumbricoides, which occurs in the hog, and on account of its identity with the same worm in the human being is specially adapted for such purpose.

Of all the substances examined, sublimate and nicotin proved themselves the most powerful; soda lye, which destroys the covering integument of the animals, also has a violent effect on the worms, while virulent poisons, as cyanide of potash, arseniate of sodium, strychnine, coniin, physostigma, aconitin, morphine, picrotoxin, evinced comparatively little effect. The same may be said of chloral, alcohol, helleborin, chlorbarym, quinine, camphor, while the animals proved very sensitive to acids, phenol and salicylic acid.

Of special interest are the results obtained with santonin. This proved not to be a remedy which has a fatal effect on the worms, but one which drives them out of the intestines. In consequence of unknown reasons the presence of santonin in the small intestine makes the worms so uncomfortable that they quickly descend into the large bowel, where they must be driven away by purgatives. Whenever, therefore, santonin is administered, it should be accompanied by a purgative, or the latter be sent after it within an hour or two.

Case of Curious Malformation of the Thorax in a New-Born Infant.

Dr. Ridley Dale thus writes in the *Med. Press:*

On Wednesday, February 17, I was requested to attend Mrs. D. in her confinement. This was her ninth child, all the others having been born perfect, and all have been strong, robust children. The labor was a natural one. On examining the child after birth the left side of the thorax presented a curious condition; for a space of four inches, extending from just above the navel to the inter-mammary line, the skin and thoracic parietes were completely wanting. The gap measured two and a half inches at the lowest part, and one and a half inches above. Below could be seen the diaphragm covering the stomach and liver, while above this the

heart protruded, being simply suspended in a horizontal position by the great vessels.

There was no pericardium. It was to me an uncommon experience to see the heart beating outside the chest for some minutes after the child was born. Respiration did not occur. After death I could replace the heart within the thorax, but on releasing the pressure it immediately shot forwards again. The ribs on the left side ceased at the border of the gap. The child otherwise appeared healthy and at its full time—thus for nine months of intra-uterine life it had lived in this condition.

This case is interesting from a medico-legal point of view, as it is possible that the appearance might be mistaken for criminal violence. No post-mortem was permitted.

Surgical Affections in the Insane.

Dr. Giné y Partagas, physician to the Barcelona Asylum, Nueva-Belén, in a clinical lecture published in *La Independencia Médica*, gives a *résumé* of the more important surgical maladies he has met with among lunatics. Erysipelas, he says, and especially erysipelas of the face, is very common, and should be watched for by the physician, as lunatics frequently do not trouble themselves about cutaneous affections. Eczema also is very common. As to furunculosis, he remarks that he has never seen it followed by cure or alleviation of the mental condition. The chief self-destructive propensity of melancholics seems to be to mutilate the genital organs. One man showed the doctor, as an evidence of his operative skill, a testicle which he had contrived to excise with the help of a piece of broken glass. Another patient managed with a similar instrument to perform a true œsophagotomy. Dr. Giné remarks that it is wonderful how insensible they seem to the pain they thus inflict upon themselves. With regard to the difficulty of retaining splints on fractures, he says that for many years poroplastic appliances have been employed in Nueva-Belén with the most satisfactory results. In conclusion, he calls the attention of his hearers to the importance of careful examinations of the inguinal and crural regions of lunatics, who may have new herniæ or inflammations in old ones for some time without complaining.

Extraordinary Cæsarian Operation.

A contemporary quotes from *La Gazzetta degli Ospitali* the case of a patient who performed the Cæsarian operation on herself. A peasant woman, æt. 23, with a common kitchen knife, opened her own abdomen on the right side. The wound was five inches in extent. The woman then opened the uterus in the same direction, and endeavored to extract the fœtus. As this was at full term it could not be readily removed. The mother first drew out an arm and cut it off. To still further reduce the bulk, she amputated the head, and then completely emptied the womb, extracting the placenta. She bound a broad bandage very tightly round her body, hid the fœtus in the straw mattress, dressed herself, attended to some domestic duties, and on a cart went into the city. On returning home, having walked about for five hours, she vomited and fainted, and the parents called in the doctors. Thirteen hours had elapsed from the infliction of the wound, and through it the bulk of the intestines had been protruding for six hours. In the end, the medical attendants having satisfied themselves of the complete reduction of the emptied uterus, performed abdominal toilette as well as was practicable, replaced the viscera, introduced a drainage-tube, and sutured the wound. The evening temperature was 37.7°; lochia natural *per vias naturales*. The woman stated positively that she had no accomplices. The wound healed, and was only superficial on the eighteenth day after the self-performed Cæsarian operation.

Antidote to Cocaine Poisoning.

In the *London Med. Record*, Dr. F. Schilling describes a case of cocaine poisoning, coming on after the drug had been locally applied for the extraction of a tooth. The patient was a woman aged 28, in the seventh month of pregnancy. The injection of two drops of a 20 per cent. solution of cocaine caused sufficient anæsthesia for the extraction of the tooth. As the patient was leaving the room the dentist noticed that her eyes were fixed, and a few minutes after making her sit down she became unconscious, reacting to no stimulus. The injection of ether had no result. During the unconscious state, which lasted over half an hour, the breathing was quiet, the pulse 86 and regular; the eyes were wide open, with medium-sized pupils, and the conjunctival reflex had disappeared. The patient could not be roused by shouting, but after a time began to call her husband by name. Dr. Schilling, considering that the condition was due to anæmia of the brain, advised the inhalation of amyl nitrite. The first inhalation seemed to rouse her, and after the second she could

answer questions hesitatingly but correctly. She was well in a short time. As the author states, it is a question whether the symptoms were not due to shock, as the patient was pregnant. He, however, considers this an improbable explanation.

Lanolin an Old Remedy.

The *Pharmaceutical Record* says:

It appears that lanolin is not entitled to take rank among the most recent additions to the materia medica, inasmuch as Culpepper, the venerable "student in physick," described it in his work published in 1650. This has been lately pointed out by a correspondent of the *Chemist and Druggist*, who gives the following extract:

"*The Way to Make Œsipus.*—Take wool cut off from the neck ribs, ribs, and under the pits of the forelegs of a sheep not washed, but well wearied, wash it well in warm water so long till it have left all its fatness in the water, then press it out and lay it by, let that fat and foul water be poured from on high out of one vessel into another a long time till it be frothy, then let the froath settle, and take off the fat that swims at the top, then pour the water to and fro again, till neither more fat nor froath appears, then wash the froath with the fat in cleer water till it be cleansed from the dross and will not bite your tongue if you touch it with it; then keep in a thick earthen clean pot in a cold place."

Measurement of the Breast.

In the *St. Louis Med. and Surg. Jour.*, for April, F. L. J. says that it frequently becomes desirable, as for instance, after Estlander's operation, to keep track of the shrinkage or other changes in the size or shape of the chest. A very simple method of accomplishing this is from time to time to make a plaster cast, of limited width, of the surface which it is desired to measure. To do this, take a roll of bandage from one to two inches wide, and, after passing it through plaster (as in preparing a plaster bandage), lay it on the surface to be measured, folding it on itself backward and forward until a half-dozen or more thicknesses have been superimposed. After the plaster has set, remove the splint thus formed and make a tracing of the inner curve. By comparing the tracing thus obtained, very accurate results may thus be secured. This idea was first suggested, but in another form, by Dr. Le Fort, in a communication to the Société de Chirurgie. Dr. Le Fort's idea is to take a full plaster cast of the chest, and then make sections of the cast.

Suppuration Connected with the Antrum Arising from Diseased Teeth.

Amelia B., æt. 22, a dressmaker, was admitted on May 1. When fourteen years of age patient had a slight abscess over the right superior maxilla, and after that had disappeared she noticed a small hard lump in this situation. This remained the same size until six months ago, when it increased in size. On admission a swelling was found over the right upper maxilla, which did not infringe on the orbit or nose. Some time ago it was larger than at present. On looking into the mouth the two right upper bicuspids were found to be carious. There had never been any discharge into the mouth or nose, but the previous Sunday for the first time a little blood welled up into the inner canthus of the right eye. The patient has always enjoyed good health with the exception of this swelling. On the 2d the patient was anæsthetized, and Mr. Bloxam ascertained that the tumor was connected with the antrum of Highmore. The carious teeth were removed, and about an ounce of watery pus drained away. The antrum was syringed out with a weak solution of permanganate of potash. The patient left cured on the 8th.

Inequality in the Length of the Tibiæ.

A boy, æt. 10, whose left tibia had grown three-quarters of an inch longer than the opposite one in consequence of stimulation of the lower epiphysis, owing to inflammation and necrosis of the shaft of the bone, was shown to the Medico-Chirurgical Society by Professor Annandale. As a result of this lengthening of the tibia, the foot had been gradually displaced outwards, so as to form a kind of talipes valgus. In order to remedy this deformity it was necessary to lengthen the fibula, and he did this by dividing the fibula at the junction of its lower and middle thirds. In addition, division of the peroneal tendons was required before the foot could be brought into position. The result had been most satisfactory, and the deformity was now quite relieved.

Successful Treatment of Cirsoid Aneurism.

Before a recent meeting of the Medico-Chirurgical Society of Edinburgh, Professor Annandale showed a woman, æt. 22, illustrating the successful treatment of a cirsoid

aneurism by a combination of electrolysis and ligature of the chief artery passing to the tumor. The aneurism involved the left upper eyelid, and passing from it over the left forehead and temple were several large, tortuous, dilated, and strongly pulsating arteries. One application of electrolysis and the ligature of the temporal artery completely cured the case. Mr. Annandale remarked that he had successfully cured several cases of cirsoid aneurism by electrolysis alone, but that this was the second case in which he had employed ligature of the artery in combination with it. In the other case the tumor was much more extensive, and he ligatured the common carotid, and also employed electrolysis with complete success.

Palliative Treatment of Uterine Cancer.

The *Med. Press* tells us that Prof. Sireday uses a very simple but effective palliative treatment for cancer of the womb, and in the many cases in which he applied it the patient's sufferings were rendered very supportable. His method consists in washing out the vagina by a solution of corrosive sublimate (1:3000), and in applying small plugs of cotton imbibed in a four per cent. solution of chloral and dusted with iodoform, to the wound. It is essential that the wound should be exactly covered with the first plug and left *in situ* for two days, when the dressing is renewed. After a few days of this treatment the ulcer, which hitherto wore a very ugly aspect, becomes clean and resembles an ordinary wound, and the pain is greatly lessened. By this method also hemorrhage is arrested, and thus the life of the patient is prolonged and her general state is greatly improved.

Recovery from Complete Alopecia of the Scalp.

To the Carlisle (Scotland) Medical Society Dr, Lediard showed a patient recovering from complete alopecia of the scalp. The woman had been under observation for two years. It commenced with one patch, and in a few weeks all the hair disappeared from the scalp, eyebrows, and eyelids. It was associated with headache. No history of syphilis. After six months hair began to grow scantily over the scalp. For a year there was a scanty growth of white hair, and during the last few months pigment has appeared in the hair, and the hair has grown more in patches. Blisters, spirit lotion, and repeated shaving, have constituted the local treatment; while quinine and iron, bromide of potassium, and iodide of potassium, have been administered internally.

A Case of Vaginitis Due to the Presence of Red Ants in the Vagina.

To the Obstetrical Society of New York Dr. Gillette reported the case of a patient who applied to him, complaining of irritation of the vulva and vagina, accompanied by profuse leucorrhœa. On examination, the vulvo-vaginal mucous membrane was found to be much inflamed, and bathed in pus. Vaginal injections were ordered, but the patient objected to them, saying that they always made her worse. A few days later she reported again, and said that she had discovered the cause of her trouble, viz, red ants had taken up their abode in her fountain-syringe, and every time she used the syringe, the ants were poured into the vagina. Their bites undoubtedly caused the inflammation. He related the case merely to offer a new cause of vaginitis.

Cardiac Changes in Typhoid Fever.

A very unusual lesion has recently been pointed out by Dégérine as occurring in the muscular structure of the heart during the course of typhoid fever. On examining the hearts of two patients who died suddenly during apparent convalescence from this disease, extensive microscopic changes were detected into the myocardium. In both cases, the lesion consisted in a separation of the intercellular cement of Eberth, which, in a normal condition, unites the cells of the cardiac fibres. There was neither fatty, putrid nor pigmentary degeneration. It is due to the solvent action of sarcolactic acid, which is formed in great abundance in the intercellular cement. No bacilli were found in the myocardium. Similar changes have been detected in the myocardium after pericarditis by Lundrouzy and Renant.

Treatment of Diabetes.

At the fifth German Congress for Internal Medicine (*Med. Record*), Professor Stokvis, of Amsterdam, discussed this subject. The speaker followed Bouchardat and Cantani, prohibiting the carbo-hydrates absolutely, and he was pleased with the results so far obtained. He insists upon muscular exercise, by which alone the percentage of sugar can be greatly diminished, regulates all the other functions of the system, and counsels also moderation in eating and all other matters. Such general treatment is particularly

adapted to fat and gouty patients, when they show symptoms of diabetes.

Wound of the Fœtus in Utero.

At the Societe de Chirurgie (Paris) M. Berger mentioned a very extraordinary case of a wound reaching the fœtus *in utero*. A woman eight months *enceinte* received a knife stab in the gluteal region, which gave issue to nearly a quart and a half of blood. The following day she gave birth to a still-born child, which presented a wound an inch in length on the right parietal bone. The peritoneum was not touched by the instrument.

Genital Irritation.

We have more than once called attention to the effects of reflex irritation from the genital organs, from a contracted prepuce, a stricture, a collection of smegma, and the like, in the causation of convulsions and a variety of phenomena, very obstinate and unyielding until the cause is discovered and removed. Do not forget this potent agency, and be ever on the lookout for it in puzzling cases.

Correspondence.

Lanolin an Old Remedy.

Eds. Med. and Surg. Reporter:—

In a paragraph which appears in the June number of the *Druggist's Circular*, some one has brought to light the curious fact that the substance recently brought to notice under the name of lanolin by Prof. Leibreich, was known and its method of manufacture described by the ancients. Upon looking over an old book, published in 1685, in my possession, I find a very similar description to that alluded to, which, for the benefit of those who may not have seen it, I will copy verbatim:

"Oesipus, sordes, or filth sticking to the wool. It is thus prepared: Take the greasie Wool from the Neck, Shoulder-pits, and Thighs of the Sheep, put it into very warm water for eight or ten hours, then boyl and stir till all the fat or greasiness is in the water; press out the wool, pour the fat and filthy water from one vessel to another till it froth; let the froth settle, take away the fat that swims on the top; pour and re-pour it as before till it froth; which repeat so often till no more froth appear, nor fat swim at top; then take the fat with the froth, and wash it up and down with the hands in clear water so often and so long till the filth is washed from it, which is when the water remains clear and the fat white, and being tasted, does not bite your tongue."

From which it would appear that the modern product, in point of color and odor at least, possesses no advantage over the ancient "oesipus."

In the chapter on "cerecloths" appears the formula for a cerate or ointment having this substance as the base, and bearing the title "Ceratum Œsypatum Mesuœ."

The excellent and, so thought, novel idea of treating skin diseases through the medium of "medicated soaps" also finds precedence in the following "soap against the itch," taken from the same book: "Sapo ad Pruritum." "Take sal regale ʒss.; burnt alum, Benjamin, liquid storax, ana ʒij.; flos. sulphuris ℈ij.; storax, calamita, litharge, ana ʒss.; dock roots ℈j.; mercury precipitate gr. v.; oyl of cloves gtt. iij.; Venice soap q. s. Make wash balls," and others as "Sapo Cosmeticus Prevotii," etc., etc.

The history of invention and discovery everywhere and in all departments of science, gives unmistakable examples of this tendency to repeat itself, and from the above it would seem that the medical art furnishes no exception to the rule.

G. A. Hill, M. D.

Williamsport, Pa., June 9, 1886.

Amputation Above the Elbow.

Eds. Med. and Surg. Reporter:

On April 13, I was called to see Mr. Thos. Stites in consultation with Dr. L. Bush, of this place. He was suffering from gangrene of the left fourth finger. On inquiring into the history of the case, I learned that fifty-seven years ago, at the age of ten, he sustained a fracture of the left ulna, severing the olecranon process. The fracture was set, and upon uniting, there was a deformity. The adhesions were then broken up and the fracture was reset. The parts united by a capsular ligament, giving the joint a ball-and-socket motion. Apparently the blood-vessels and nerves had been injured, since there was a partial loss of sensation and impaired nutrition; the forearm and hand being considerably smaller than the corresponding parts of the opposite side. Not being able to check the gangrene, we decided to amputate the arm just above the elbow, which we did on April 21. In amputating I made the flaps by the method of Mr. Liston. Fearing some sloughing in consequence

of his age, I made them in length one-fourth the circumference of the limb. There was no sloughing, however, but enough contraction to form a good stump. Notwithstanding his age, at the end of four weeks the parts were healed with the exception of a small granulating surface externally. I prefer goodly-sized flaps, so that we will have something to fall back upon, since it would be much easier to remove a portion of a redundant stump than to reamputate, which latter is frequently necessitated in consequence of unlooked-for sloughing or contraction.

N. C. Miller, M. D.

Stroudsburg, Pa., June 4, 1886.

Coffee a Cause of Pruritus and Leucorrhœa.

Eds. Med. and Surg. Reporter:

Seeing an editorial in the Reporter, June 5, noticing observations of Dr. Brown-Sequard regarding the connection between coffee and pruritus in certain nervous subjects, I present two cases coming under my care, involving not only pruritus but also leucorrhœa. I have seen several since, but not so marked.

Case 1. A young lady, never accustomed to drink coffee at home, was sent to Germany to complete her education, went to a boarding-school, entirely isolated from family and friends, and had coffee three times a day as a common beverage. Within two weeks had an aggravated case of pruritus and leucorrhœa, which lasted despite treatment, during her two years' sojourn. Returning home, became entirely well within a short time, having had no coffee. The family breaking up a few years later, she went to board, resumed the habit, and the trouble returned. Numerous experiments proved the cause. To-day a cup of coffee in the morning will cause a return of the trouble before night.

Case 2. A young lady from the South, an habitual coffee-drinker, had pruritus and leucorrhœa since a child. Was never benefited by treatment. Coming under my care, I advised her to give up the habit. She did so, and received immediate benefit. Both were of a nervous temperament.

A. K. MacDonald, M. D.

Princeton, N. J., June 14, 1886.

—The forty-five million population of the United States have 89 regular medical colleges, with about 10,000 medical students; 8 of these medical colleges have each from 300 to 600 students, and 7 of these colleges have from 200 to 300 students.

News and Miscellany.

Ninth International Medical Congress, Washington, 1887.

RULES FOR THE GOVERNMENT OF THE LOCAL COMMITTEE OF ARRANGEMENTS OF THE NINTH INTERNATIONAL MEDICAL CONGRESS.

The following order of business shall be observed:

1. Reading the minutes of the previous meeting.
2. Reports of sub-committees, in order.
3. Unfinished business.
4. New business.

Meetings.

The meetings shall be held at such time and place as the Chairman or, in his absence, the Secretary shall select.

A majority of the General Committee present at any meeting shall constitute a quorum authorized to do business.

No member shall be permitted to speak more than five minutes on a single question.

The Officers.

The officers of this committee shall consist of a Chairman, Vice-Chairman, Secretary, and Treasurer.

Duties of the Officers.

The Chairman shall preside at all meetings, preserve order according to parliamentary rule, approve the necessary requisitions and vouchers, and all official communications to the Executive Committee shall emanate from him. In the absence or disability of the Chairman, the Vice-Chairman shall perform the duties of the Chairman for the time being, and in the event of his absence or disability a Chairman *pro tempore* shall be elected by the committee.

The Secretary shall keep a true record of all proceedings, notify the members of the times and places of meeting, and such other duties connacted with his office as the committee may, from time to time, direct.

There shall be elected a Treasurer, whose duty it shall be to receive from the Finance Committee all moneys collected for the expenses of the committee, and to pay the same by check on vouchers duly certified by the Chairman of the Committee of Arrangements and the Chairman of the Finance Committee. He shall deposit all sums of money received by him from whatever source in Riggs & Co.'s bank, keep book of deposits and vouchers of all payments made by him.

Sub-committees.

The following sub-committees shall be recognized:

1. Committee on Congressional Legislation.
2. Committee on Finance.
3. Committee on Printing.
4. Committee on Reception.
5. Committee on Entertainment.
6. Committee on Transportation.
7. Committee on Place of Meeting for Congress and its Sections.
8. Executive Committee.

DUTIES OF SUB-COMMITTEES.

Committee on Congressional Legislation.

To this committee will be assigned the work of applying to the Congress of the United States to aid in meeting the expenses of receiving and entertaining in a manner commensurate with the dignity and pride of the United States Government, the International Congress here in America.

Committee on Finance.

This committee will be entrusted with the duty of collecting funds from whatever source it may see proper to apply (the U. S. Congress excepted) for the expenses to be incurred by the Local Committee of Arrangements, and all moneys so collected must be paid into the hands of the Treasurer at the end of each week, the chairman of sub-committee taking a receipt for the same and keeping an account of source from whence collected.

Committee on Printing.

This committee shall have charge of all printing necessary for the official business of the committee, blank-books and stationery, and shall furnish the same to the various committees on requisition of the chairmen of sub-committees, approved by the Chairman of the Committee of Arrangements.

Committee on Reception.

This committee will be intrusted with the duty of making all suitable arrangements for the accommodation of members of the Congress, and establishment and maintenance of a bureau of information for the members and guests of the Congress.

Committee on Entertainment.

This committee shall devise and arrange such plan of excursions and other entertainments as they may see fit to propose to the General Committee for its adoption.

Committee on Transportation.

This committee shall have charge of all matters pertaining to transportation of members of the Congress to and from the city of meeting, and of excursions, and shall see that accurate information upon this subject be supplied, not less than one month in advance, to all American members who may signify their purpose to attend the meeting in this city.

Committee on Place of Meeting for Congress and its Sections.

The duty of this committee will be to provide a suitable hall for the meeting of the Congress, as well as convenient and eligible rooms for the different Sections, and to make such arrangements as may be necessary for an easy access to the same by the members of the Congress.

Executive Committee.

The original committee of six, appointed by authority of the Executive Committee of the International Medical Congress, shall constitute an Executive Committee, whose duty it will be to act as an Advisory Board or Judicial Council, and determine the settlement of all miscellaneous questions referred to them.

All contracts involving expenditures by sub-committees shall be subject to the approval of the Executive Committee.

LOCAL COMMITTEE OF ARRANGEMENTS.

Chairman.—A. Y. P. Garnett, M. D.
Vice-Chairman.—J. M. Toner, M. D.
Secretary.—C. H. A. Kleinschmidt, M. D.
Treasurer.—D. C. Patterson, M. D.

EXECUTIVE COMMITTEE.

Dr. A. Y. P. Garnett, Dr. J. M. Toner, Dr. N. S. Lincoln, Dr. C. H. A. Kleinschmidt, Chief Medical Purveyor J. H. Baxter, U. S. Army; Surgeon-General F. M. Gunnell, U. S. Navy; Surgeon-General Robert Murray, U. S. Army; Supervising Surgeon-General J. B. Hamilton, U. S. Marine Hospital Service.

1. *Committee on Congressional Legislation.*—Drs. Garnett, Baxter, Walsh, Townsend, Toner, Lincoln, Hammett.

2. *Committee on Finance.*—Drs. G. L. Magruder, J. T. Young, Z. T. Sowers, J. W. Bulkley, T. C. Smith, J. W. Bayne, C. V. N. Callan.

3. *Committee on Printing.*—Drs. J. B. Hamilton, W. T. Hord, U. S. N.; Thos. Antisell, D. P. Woolhaupter, Ralph Walsh, H. D. Fry.

4. *Committee on Reception.*—Drs. J. M. Toner, S. O. Richey, H. B. Loring, I. C. Rosse, Fairfax Irwin, M. H. S.; Louis Mackall, B. O. Skinner, U. S. A.

5. *Committee on Entertainment.*—Drs. N.

S. Lincoln, W. W. Godding, C. M. Hammett, W. O. Baldwin, G. W. Acker, D. R. Hagner, D. C. Patterson.

6. *Committee on Transportation.*—Drs. J. W. H. Lovejoy, Armistead Peter, W. H. Taylor, Geo. W. Stoner, M. H. S.; R. Reyburn, Sr., E. M. Schaefer.

7. *Committee on Place of Meeting for Congress and Sections.*—Drs. D. C. Patterson, J. F. Hartigan, C. W. Franzoni, Chas. Smart, U. S. A.; J. O. Stanton, W. H. Hawkes, Lachlan Tyler.

How the Founder of the Society of Friends Set a Dislocated Neck.

The *Med. Record* says: "In an interesting and scholarly address by Dr. J. J. Levick, on the 'Early Physicians of Philadelphia,' he tells us how George Fox traveled through New Jersey and New England, keeping a faithful journal of all that occurred. 'In 1672 he was passing through New Jersey, then but sparsely settled. He had spent the day with Richard Hartshorne, at Middletown Harbor (the ancestor, if I mistake not, of one of our present Board of Managers, and of three physicians of that name who have so well served this hospital), and next morning went on to Shrewsbury. "While at Shrewsbury," writes Fox, "an accident befell which for a time was a great exercise to us. One John Jay, a Friend of Barbadoes, who came with us from Road Island, being to trie a horse got upon his back, and the horse fell a running and cast him down upon his head, and brake his neck, as the people said. They that were near him took him up dead, and carried him a good way, and laid him on a tree. I got to him as soon as I could, and feeling on him, concluded he was dead. As I stood by him, pitying him and his family, I took hold of his hair, and his head turned anyway, it was so limber. Whereupon throwing away my stick and my gloves, I took his head in both my hands, and setting my knees against the tree, I raised his head and perceived there was nothing out or broken that way. Then I put one hand under his chin and the other behind his head, and raised his head two or three times with all my strength and brought it in. I soon perceived his neck began to grow stiff again, and then he began to rattle in his throat, and quickly after to breathe. The people were amazed, but I bid them have a good heart and be of good faith; to carry him in the house, give him something warm to drink, and put him to bed. After he had been in the house awhile he began to speak, but did not know where he had been. The next day he was pretty well, and many hundreds of miles did he travel with us after this."'"

Spanish Medicine.

The *Lancet*, May 8, says:

Don Luis Comenge has recently published a Spanish work, entitled "Medical Curiosities, preceded by a Discourse on the Flourishing Condition of Spanish Medicine in the Sixteenth Century and its Subsequent Decadence." Though entitled "Curiosities," there is much serious medical history which, as a reviewer in *El Genio Medico Quirurgico* says, deserves to be read and pondered over, such as descriptions of those who have contributed in past ages to the advancement of medical knowledge, and accounts of their doctrines and works. One chapter is devoted to the history of variolous inoculation, which was commenced in Spain, by Dr. O. Scanlan, and a parallel is drawn between the arguments of the anti-inoculationists of those days and the anti-vaccinationists of the present time, together with the opponents of Ferran's anti-cholera inoculations. With regard to decadence of Spanish medicine since the sixteenth century, the reviewer referred to remarks: "Until instruction undergoes a complete change, we shall not advance a step in the direction of progress. Medicine has for some years been in the stage of pure experimentalism, and we Spaniards experiment but little or not at all. In the professoriate there are, it is true, many men of profound knowledge, who are an honor to contemporary medicine; but there are still others who talk to their students about the pathogenetic importance of phlegm, and lecture on typhus, cholera, and other infectious diseases just as teachers at the commencement of this century might have done." With such elements in the professional staffs, the author and reviewer agree that but little progress is to be hoped for.

The Influence of Water on Nutrition.

At a recent meeting of the Société Médicale des Hôpitaux (Paris), M. Debove stated that so many objections had been raised against the method which he had adopted in making his experiments to ascertain the influence of water on nutrition, that he had subsequently made a fresh series of control experiments. In this series, he had selected none but perfectly healthy individuals. These persons were fed on raw meat, new bread, and water. Either raw meat or meat

boiled to shreds must be given, because both the chemical constitution and nutritive qualities of meat vary according to the way in which it is prepared. The daily bread should always be equally well baked. M. Flameng, M. Debove's house-surgeon, adopted a uniform diet for thirty-eight days. When he reached a weight that remained stationary, the allowance of water was doubled and trebled, but the rations of bread and meat remained the same. During the second part of the experiment, neither the weight nor the excretion of urea increased. Two other persons were submitted to the same treatment. Their weight also remained stationary, as did the quantity of urea excreted. M. Debove therefore concluded that the ingestion of more or less large quantities of water did not exert any influence on nutrition, when the quantity reached a certain degree. He admitted, with Dr. Dujardin-Beaumetz, that entire abstinence from water would disturb the digestive faculties. Therefore, persons deprived of water grew thin.

Artificial Coloring Matters in Wine.

Dr. C. Blarez sends to the Bordeaux Medical and Surgical Society, in support of his candidature, a paper embodying the results of various observations he has made on the subject of the noxious effects produced by drinking liquids colored with certain coloring matters derived from coal. Many of the observations were made on persons who, being medical or pharmaceutical students, were excellent subjects for the purpose. A number of experiments were also made by artificially carrying on the process of digestion with and without the addition of the coloring matters in question. The conclusions arrived at were that sulpho-fuchsine, which seems to be used for the coloration of of wine, though it can hardly be looked upon as a poison, is nevertheless capable of setting up a good deal of gastric disturbance, especially if taken habitually by persons whose digestive powers are not very strong, the symptoms produced being generally colic and diarrhœa. The author found that this substance, as well as "Bordeaux red" and safranine, distinctly retarded the peptonization of muscular fibrine.

Electricity in Physiology.

Dr. Stone, in his Lumleian Lectures, has certainly not wanted the courage of his opinions. He has approached the study of the electrical condition of the human body from the purely physical side, and has exposed unsparingly the fallacies into which he believes physiologists have been led, by neglecting thoroughly to understand the physical characteristics of the force which they have used. His contention is, that a force, whose phenomema are undoubtedly very complicated, and but imperfectly understood, has been used for the study of phenomena even more complicated and less understood. The science of electricity, partly, it must be admitted, under the stimulus of commercial necessities, has, in recent years, made great progress, and some of its discoveries and inventions, it is said, place in the hands of physiologists new and more accurate instruments of research, and refined methods of eliminating fallacies. Modern students of medicine are increasingly overwhelmed with details about the electrical phenomena of muscles, and so forth, and Dr. Stone's lectures may, perhaps, serve to suggest to teachers of physiology the advisability of ceasing the customary annual increment of facts of this class, which so remotely affect practical medicine, until their truth is a little better established.

Unqualified Masseuses in Vienna.

A Vienna medical journal complains bitterly of the patronage afforded to quackery in the form of massage by medical men of the highest position—professors, lecturers, and others—who assist in setting up their female relatives or servants in business for themselves as *masseuses*. Massage is not a treatment which can safely be trusted to a lay person. It requires a knowledge not only of normal anatomy, but of the nature and course of the disease from which the patient is suffering. As these persons frequently practice without reference to a medical man, it is not surprising that they sometimes go on "massiring" a malignant tumor or a case of tuberculous periostitis for weeks or months, and so do a great deal of harm. "It is a great pity," continues the journal referred to, "that people have taken it into their heads that it is undignified for a physician to practice massage. Men like Mesengeil in Bonn, Busch in Berlin, Bergmann in Stockholm, Johnsohn in Copenhagen, etc., have not been above practicing massage. It is greatly to be desired that the medical authorities may see their way, in the interest of the suffering public, to bring this new form of quackery within narrower bounds."

The Imperial University of Japan.

The Imperial University of Japan has

been recently reorganized. One of its most important departments is the College of Medicine, which is presided over by Dr. Miyake. The main course of instruction is modeled after that in the German medical colleges; the foreign professors, of whom there are at present also five, are also German. The course covers a period of four years, and the preparatory course three years more. There is also a course of lectures delivered in the vernacular, which is called the special course. The total number of students last year was nine hundred and seventy-two. The medical school of Japan is eleven hundred years old. In its early days it was presided over by a superintendent and an assistant, under whom there was one professor of medicine, one of acupuncture, one of massage, one of diseases of women, a teacher of materia medica, botanists, and a number of physicians. The whole course covered seven years.

A Russian View of the Berlin M. D.

The Berlin correspondent of a Russian medical journal makes merry over the mediævalism still lingering in Prussian universities, and especially over the ceremony of the disputation for the doctor's degree, with the dean in his red robes merely playing propriety with classical Latin phrases, and the candidate with his three "friend opponents," who have settled with him about the subjects to be discussed beforehand. All this, says the correspondent, is very different from the procedure in Russia, where there are no traditions handed down from the middle ages to be attended to, and the professors are much stricter about allowing candidates to pass, besides which the young aspirant has, instead of friendly opponents as youthful as himself, masters of the art of wrangling to contend against. Altogether, the writer seems to think it hard that the title of doctor can be obtained on so much easier terms abroad than in Russia. Comparisons are proverbially odious. It would be instructive to see what Berlin graduates acquainted with the proceedings at Russian universities have to reply to the criticisms of their Russian visitor.

A Simple Method of Keeping the Hypodermic Syringe in Order.

Dr. D. Tod Gilliam, of Columbus, O., writes to the *Med. Record*: "A simple and efficient method for keeping the hypodermic syringe in order is as follows: Draw out the piston-rod, immerse the syringe in water, then push the piston home, when the chamber of the syringe back of the piston-head will be found filled with water which entered at the orifice through which the rod plays. This will not leak out, will keep your syringe in prime order, ready for any emergency, and will save money as well as annoyance by enabling you to use a syringe that would otherwise be discarded. As the device is so simple, entails no trouble, and the syringe being once filled need not be looked after for weeks or months if need be, I thought it worth mentioning."

A Child Poisoned by the Nurse's Cosmetic.

The *Med. News* says that a German practitioner being called to see a child five weeks old who was constantly crying and suffering from colic, and whose skin was of a dull bluish tint, was somewhat puzzled as to diagnosis, until, looking at the nurse's face, and seeing it of a brilliant white and red tint, he touched the surface, which left a greasy stain on his fingers of a cosmetic rich in lead. This poisonous substance the nurse had long been in the habit of using for the purpose of improving her complexion. The cause of the child's colic being removed, and appropriate treatment adopted, a cure was effected in a few days.

The Cocaine Habit.

The *Med. Record* says that no drug with so short a history has gotten hold of so many victims as cocaine. We fear that the cocaine habit has a great and gloomy future before it. It is a habit more easily acquired and one which ruins body and mind even more quickly than does morphine. We make these comments *a propos* of a shocking case recently reported in a city in Central New York. A physician and his daughter were reported to have gone to a hotel and there have exhibited almost maniacal symptoms from the effects of cocaine. Both had been taking it in immense doses subcutaneously for some time.

Effect of Light on Bacillus Anthracis.

According to M. Arloing, gas-light is slightly prejudicial to the growth of the bacillus anthracis. The sunlight of summer suppresses the vegetation of the spores if the rays of light can penetrate easily the fluid media that hold the bacillus in suspension. Sunlight also interferes with the growth of the mycelium, and is an agent as effective as heat for the attenuation of the

virus of charbon. The effect of sunlight is due to the action of all its component rays; the effects are proportional to the intensity of the light and the transparency of the media.

Extraordinary Subject for a Prize Essay.

The Paris Academy of Medicine has chosen an extraordinary, not to say an impossible subject for a prize essay this year, "Préciser par une Série d'Observations s'il existe un Traitement Abortif de la Syphilis Confirmée," (to determine by a series of observations if there exists an abortive treatment of confirmed syphilis), upon which M. Diday has suggested that the Academy must have been seized with an economical fit, and that it would be interesting to see if any one could manage to write a paper of 400 pages of abortive treatment directed against confirmed syphilis.

Therapeutic Notes.

SUMMER CHOLERA.

In the summer diarrhœa of infants and in cholera morbus, a well-ordered diet is of the highest importance. Among other articles, "Nestle's Milk Food," which is advertised on another page, occupies a deservedly high rank as a bland and nutritious food for delicate stomachs.

The New York *Medical Journal* states that in the large class of summer diarrhœas of children and adults, with griping in the bowels and flatulence, the use of Listerine, in doses varying from ten drops to a teaspoonful (with or without water), has a most salutary and pleasing effect.

Old Age in St. Petersburg Poorhouse.

According to the *Novosti* a man has just died in the St. Petersburg poorhouse at the age of 122; he had been an inmate since 1818. He retained his senses to the last. Indeed, it was only about four years ago that he seemed to fail at all, having till then enjoyed excellent health. There is still living in the poorhouse a soldier's wife, who is shown by documentary evidence to be fully 110 years of age.

On the Alleged Fragility of the Bones of General Paralytics.

T. Christian says (*Journal of Mental Science*, vol. xxxi., p. 453,) that out of 250 general paralytics under treatment, not a single case of fracture occurred. General paralysis does not in itself entail any increased fragility of the bones, and osteomalakia, when present, is a purely accidental phenomenon, the result of other causes.

Items.

—In the *Jour. Am. Med. Ass.*, May 8, Dr. Wm. G. Eggleston reports two cases of reflex paraplegia (one with aphasia), from tape-worm and phimosis.

—It is said that stove-pipes can be cleaned by putting a piece of zinc on the coals of a hot fire. The vapor produced carries off the soot by chemical decomposition.

—The Municipal Council of Paris has voted the sum of 4,500 francs to defray the expense incident to making a complete statistical review of the cholera epidemic of 1884–1885, in that city.

—The Mississippi Valley Medical Society will hold its next meeting at Quincy, Illinois, in the court house, July 13, 14, and 15. Special fares on railroads can be obtained by addressing the Secretary, Dr. Robbins, at Quincy.

—On the occasion of the tercentenary festival of the University of Heidelberg, a gold medal was founded for contribution to the scientific knowledge of the human eye. The first award has now been made to Professor Helmholtz, of Berlin, for his discovery of the ophthalmoscope.

—Mr. Leland Sanford, wife of the millionaire Senator from California, has purchased a piece of land on Washington Avenue, Albany, adjoining the site of the old Lathrop mansion, and it is stated on the whole property she will erect a handsome and well-appointed hospital for old men and women, as a memorial of her parents.

—A subscription for the purpose of encouraging researches in the therapeutics of tuberculosis has been opened by the *Gazette Hebdomadaire de Mèdecine et de Chirurgie*, of Paris. The idea of a subscription for this purpose was suggested by M. Verneuil, and in a few days the sum of over four thousand francs was raised.

—In the *Lyon Médical* and *Journal de Médicine* for March 27, Aubert states that headache and coryza resulting from full doses of iodide of potassium can be prevented by using belladonna. In one instance, in which five grammes of the iodide were administered daily, six grammes of extract of beliadonna were also given. A few days later the belladonna was discontinued, and iodism did not return.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to maintain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

Lecture.

LECTURES ON INSANITY.

DELIVERED AT THE UNIVERSITY OF PENNSYLVANIA.

BY CHARLES K. MILLS, M. D.,

Lecturer on Mental Diseases in the University of Pennsylvania; Consulting Physician to the Insane Department of the Philadelphia Hospital; Neurologist to the Philadelphia Hospital; and Professor of Diseases of the Mind and Nervous System in the Philadelphia Polyclinic.

Reported by William H. Morrison, M. D.

Lecture X.

CONTRACTS WITH THE INSANE—BUSINESS CONTRACTS—ILLUSTRATIONS—MARRIAGE CONTRACTS—RHINELANDER CASE—CASE OF MARRIAGE AFTER A PARALYTIC ATTACK.

Gentlemen: In several preceding lectures I considered the methods of admitting and discharging insane patients from asylums or hospitals; the placing of insane under legal control; and also in the last lecture I discussed some of the dangers which physicians run in the performance of these duties, giving illustrations drawn from some recent experiences. I cannot too strongly impress you with the importance of conscientious care and watchful precautions for your own sakes, as well as for the sake of justice to your patients.

To-day I shall direct you to two new questions. The first is that of business, marriage, and other contracts with the insane. The second is that of wills and the testamentary capacity of the insane.

Following the semi-clinical method which has been adopted in these lectures, I shall at once give you two or three leaves from experience. A few years ago a gentleman of this city came to me as a patient. He was at that time at the head of one of the departments of a large manufacturing establishment in this city. When he first came under observation he was suffering from posterior spinal sclerosis or locomotor ataxia. He remained in my hands for several years. About three years after I first saw him, he began to develop symptoms of insanity. These were discovered by me long before his family or those who were in business with him were willing to acknowledge that he was insane; and a comparatively long time before he was placed under restraint, I advised the family to take some legal measures in order to protect themselves. Under the influence of delusions of grandeur, which, as you know, develop sometimes early, sometimes in the middle period, and sometimes late in the disease, he began to use money extravagantly, and even attempted to enter into contracts with reference to the purchase of houses, and other contracts, which he was pecuniarly unable to fulfil. He was a man of some means, probably worth $10,000 or $12,000. He had a wife who was herself an invalid, and it was important that this little fortune should be preserved to his wife. However, no steps were taken for some time to declare him insane. In the meantime, he threw away a large portion of this small estate. Among other things that he did was to make arrangements for the purchase of two or three houses on a prominent street in this city. He was well known, and always had been a responsible man. The gentleman with whom he attempted to make the contract had some of the papers drawn up before he would listen to the statements that he was insane. It

was difficult to make this gentleman believe that he was insane, and he threatened to bring a civil suit to hold him to the bargain. On one occasion, he gathered his boon companions around him and gave them a supper. He was really forty-nine years of age, but he said that he had had such a good time that he had really lived fifty years in forty-nine, and he was going to celebrate his fiftieth birthday a year before it was due. In this way he wasted several hundred dollars. He also gave money away. He was finally certified to be insane, and was placed in an asylum.

Another case more recently under my care was that of a prominent merchant. He developed symptoms first of melancholia. He was in this condition for several months, and although much depressed, and at times exhibiting suicidal tendencies, he was able to conduct his business. Then he had a sub-lucid interval. This was followed by symptoms of acute mania, and he then began to drink freely. When the symptoms of excitement or exaltation appeared, he began to have extravagant ideas from a business point of view. He was a thorough business man, and had been in the habit of making large purchases. He now purchased large quantities of goods for which there was no need, thus entailing loss. His symptoms finally became so marked that it was necessary to send him to an institution.

Still another case which came under my observation at about the same time as the last case was that of a man, the chief buyer in a large mercantile house, although not a member of the firm. This man began to develop symptoms of general paralysis of the insane, with delusions of importance, wealth, etc. He began to imagine that enormous business in a certain line was awaiting the firm. He went to New York and other cities and made extravagant purchases. It was then discovered that something was wrong, and he was sent to an asylum.

The story is related of a paretic dement, who was a very active member of the church, and was present on one of those glorious occasions when subscriptions are solicited under excitement, for the benefit of the church and for other purposes, and subscribed very liberally, some $30,000, I think, for the enterprise then on foot. Of course, he was a very popular man on that occasion. It turned out afterwards that he was a paretic dement, who had really subscribed this amount while in a delusional condition. It is probable that it occasionally happens that great subscriptions and liberal or even extravagant donations of money are made in this way.

What about the validity of contracts of this kind? The validity of civil contracts made by the insane, like so many other questions pertaining to insanity, must be decided largely by the circumstances surrounding the particular case. While we have decisions and laws relating to matters of this kind, yet these are not so absolute, and are not rendered so closely after previous cases, but that doubts may arise in a particular case. The mere fact of the existence of insanity will not always invalidate a contract. The particular circumstances surrounding such a case must always be taken into consideration. If a merchant, although insane, made a contract, and if the party with whom the contract was made would be the loser if it was not fulfilled, the law in all probability would hold the firm to which the insane man belonged liable. In one of the cases I have alluded to, the firm did not attempt to get out of their contract, although they involved considerable loss. Some American cases hold that there can be no recovery against lunatics in cases of this kind. In certain English cases, which will be found in the ordinary text-books, the opposite has been held. When it can be shown that an individual took advantage of an insane person to make a contract in his own favor, the courts would decide against the contract.

A person who has been declared to be insane by an inquisition or commission could not, I suppose, be held responsible in a court for any contract; but in other cases it would be largely a question of argument before a jury, and of special decision by the judge.

Let us now briefly consider the question of marriage contracts, in the case of the insane. The law recognizes insanity as an impediment to marriage. The insane person is in a condition similar to that of an infant under the law, that is, one who has not reached the age of twenty-one years. A marriage contract with a lunatic whose insanity has been legally or generally recognized would not be held to be valid, yet various cases arise in which marriage contracts with the insane are considered valid.

The "Rhinelander case," was of some interest in connection with the question of marriage contracts, as well as in other respects. Mr. Rhinelander is a member of one of the wealthiest families of New York, and is alleged to be insane. From the accounts which I have read in the newspapers, and in one or two medical journals devoted to psychiatry, there would seem to be little

doubt that he is in a delusional state. He is a shrewd and, superficially, an able man. I say "superficially," because the appearance of ability in these cases is usually only on the surface. He shot a New York lawyer who was the solicitor of his father's family, and was the instrument through which money was paid to him, on the supposition or delusion that the lawyer was having improper relations with his wife. He was declared sane. The case was four days before the Surrogate, and after testimony was given by experts on both sides, and evidence as to the man's past history was offered, a majority of the commission decided in favor of his sanity and a minority against it. The Surrogate decided in favor of his sanity, and under the law he is recognized as sane. In his case certain questions in regard to marriage arose. He had married a woman supposed to be in an inferior position in life, a domestic, I believe. Efforts were made to have them separated and to invalidate the marriage contract, under the idea that it was a marriage with a lunatic. These efforts not only failed, but the proceedings to find him a lunatic also failed. While a marriage with a lunatic is unlawful, the question of insanity is not always decided in accordance with the facts by judge and jury.

Sometimes curious phases arise with reference to marriage contract. A man well known in this city, particularly in political circles, had lived for many years with a woman to whom he was not married. By this woman he had had two or three children. He led a dual life so far as society was concerned. It seemed from what transpired after his death, that some members of his own family did not know that he was living in this way. He had a house in a certain part of the city where he lived part of the time with this woman, and they were known as man and wife. He took good care of her and of the children, and was supposed by many to be legally married to her. He was stricken with paralysis some weeks before he died. I was sent for by the physician in attendance to see him in consultation with reference to the prognosis and treatment of the paralysis, but with especial reference to his mental condition. I examined him, and found him paralyzed on one side, and also found that his speech was to some extent affected, but his mind was clear for all the ordinary purposes of life. Fortunately, in examining him I became interested in his case, and made, without any idea of the legal questions which afterwards arose, some use of special methods of examination. I had him read to me from papers and books for several minutes, and also asked him questions requiring answers in regard to certain matters. I found him capable of answering questions and of reading consecutively for a certain length of time. I saw him a second time two or three weeks later. Between my two visits he was married by the priest to the woman with whom he had been living, who thus became legitimately his wife. He died, and immediately efforts were made to take out letters of administration in favor of his wife. This procedure was resisted on the part of his relatives, who had not known that he was married, and who claimed that undue influence had been used, and also that he was not in a condition of mind to know what he was doing. The case came up before the Register of Wills to decide whether or not letters of administration should be granted. The attending physician, the priest, myself, and one or two others who had known him intimately during this time, testified to the belief that he was in a sufficiently good mental condition to make this marriage contract and to understand what he was doing. This was the sole point at issue. It was not a question as to whether he was in a condition to make a will or whether undue influence had been used to induce him to make a will of a certain character. The only qusstion was whether he knew what he was doing when he was married. After hearing the testimony, the Register of Wills gave letters of administration to the wife, and the case was dropped.

COMMUNICATIONS.

MALARIAL HÆMATURIA.

J. A. STAMPS, M. D.,
Of Wallaceburg, Ark.

(*Concluded from page* 6.)

Treatment.—The first and most urgent indication is to arouse all of the emunctories to a proper performance of their work, and it would be well enough to begin with twenty-grain doses of calomel every four hours till there is a free evacuation from the bowels, it being one of the most valuable purgatives on account both of its certainty and mildness of action; it also powerfully stimulates the secretory function of the liver, and relieves portal congestion; and again, when given with other medicines, it has a peculiar property of aiding their action; "thus it

renders squills more diuretic, nitre and antimonials more diaphoretic" (*U. S. Dispensatory*, p. 1094).

Along with the calomel may be given the following, which is possessed of diuretic and diaphoretic properties: Spts. etheris nit., gtt. xx. to ʒss.; spts. ammoniæ aromat., gtt. xx. to ʒss.; aquæ, q. s., every two or three hours—the indication being to flush the kidneys by a copious flow of urine and keep the tubules cleared of those granular elements which, if allowed to remain in the tubules, would more than likely cause them to become incapable of ever performing their work in a way proper for the well-being of the individual (provided, of course, a sufficient number of the tubules are implicated to have a decided influence in lessening the capacity of the kidneys); also to arouse the skin to a proper performance of its functions, and thus lessen the strain on the kidneys.

As there is a peculiar condition of the blood-vessels, which lessens their power of retaining the blood constituents, an astringent is necessary, and for this end nothing answers, in my opinion, more admirably than gallic acid, in five-grain doses, every three or four hours. The gallic is not so strong as the tannic, yet it is preferable to the former owing to the fact of its being more readily transported by the blood, in all cases of hemorrhage where the blood-vessels must be reached through the blood. Ergot has also been used for this purpose by some, they supposing that it acted peripherally upon the vessels; but whether its beneficial effects are to be classed under the head of its peripheral action or upon its power of stimulating the vaso-motor centres, is questioned.

The next indication, or another one, for they are all very pressing seemingly, is to stimulate or arouse the vaso-motor centres to a normal performance of their functions by which the general tone of the entire vascular system may be brought up to its normal standard.

For this end ergot in ʒj doses every 3 or 4 hours may be mentioned first; not on account of its superiority to the other remedies to be mentioned, but from the fact that it is given by some, as before stated, for its direct action on the peripheral muscular coats of the vessels and nerves connected with them (the vessels). This it may do in part, but I am strongly of the opinion that it has a decided stimulant effect upon the vaso-motor centres. In the U. S. Dispensatory, p. 562, you will find the following regarding the medicinal properties of ergot, "and the most important physiological action of the drug is upon the vaso-motor nervous system.

"It has been abundantly proved that in full therapeutic doses it raises markedly the arterial pressure by producing a general vaso-motor spasm. The spasm is almost certainly the result of a stimulation of the vaso-motor nervous centres, but there are still some authors who believe that the drug acts peripherally upon the muscular coats of the vessels or upon the nerves connected with them."

Another medicine is sulphate of atropia in $\frac{1}{120}$ gr. doses every 4 to 6 hours, or in very urgent cases $\frac{1}{80}$ gr. at first dose, which has proved very successful with some members of the profession, among whom is our Vice-President, Dr. Hart, whose praise in behalf of a remedy would most assuredly allow it a place among meritorious remedies. This in moderate doses acts as a stimulant to the vaso-motor centres, and thereby causes a great rise of arterial pressure. Upon the spinal cord, it acts as a powerful stimulant.

The U. S. Dispensatory, p. 66, says: "In shock and other similar states in which vaso-motor paralysis is an important part of the morbid condition, it is a very useful stimulant."

It is eliminated by the kidneys, and may cause an increased flow of urine, and also to some extent allay the irritation which is more than likely to exist in the blood-vessels.

I will now give a treatment to which I attach a great deal of importance, having in my opinion saved a patient's life by it and very successfully treated another. It consists in the following, to wit: Upon first seeing the patient, begin with 20 gr. doses of calomel every 4 hours till four doses are given. Next begin with $\frac{1}{20}$ gr. doses of sulph. strychnia, and $\frac{1}{4}$ gr. doses of sulph. morphia every 4 hours. The strychnia acts as a powerful stimulant to the vaso-motor centres in the medulla and spinal cord. Foster's Physiology, p. 276, says strychnia stimulates both the vaso-motor centres in the medulla and spinal cord.

Strychnia is also recommended as a remedy *par excellence* for paralysis, its action being more especially directed to the paralyzed part.

The U. S. Dispensatory, p. 1370, in dealing with strychnia, says: "On account of its stimulant effects upon the gastric mucous membrane, and of its tendency to excite the vaso-motor centres of the spinal cord, and thereby increase the activity of the circulation and general systemic tone, strychnia is a very valuable tonic, which may be given along with iron and simple bitters in cases of

anæmia, especially in cases of general relaxation."

And besides these effects, it has been highly extolled as a remedy in the treatment of other forms of malaria. Now morphine is excitant in its primary action.

U. S. Dispensatory, p. 1075, says: "In low typhoid complaints requiring a supporting treatment it exalts the action of the arterial and nervous systems, and in moderate doses frequently repeated may be employed with advantage in conjunction or alternation with other stimulants."

Probably dependent upon a similar influence over the nervous system is the property which it possesses of allaying general and local irritations, whether exhibited in the nerves or blood-vessels, provided the action does not amount to positive inflammation, and even in this case it is often prescribed with advantage.

And in suppressing morbid discharges, it answers another indication which alone would answer an admirable purpose in the affection. And next to this is its power of relieving pain, for which it is unexcelled by any therapeutic agent yet added to our armamentarium of medicines which are given per orem.

Besides these effects, it seems to have some power in controlling the extreme nausea and vomiting, in small doses and not too frequently repeated; and, by the way, I have failed thus far to mention these important and very distressing symptoms, viz., nausea and vomiting, for which the various antiemetics may be of service, as peppermint, lime-water, carbolic acid, ice internally in small quantities or applied to the epigastrium or throat just above the manubrium. I however attach more faith to brom. of potash in from 5 to 20 gr. doses every 2 hours than any other remedy, for the vomiting is certainly of nervous origin, and from a trial of it in the last case that I had I was led to believe that its administration checked these symptoms, which did not return.

Quinine has been recommended by many authorities as the sheet-anchor in this trouble, while others hold to the view that it is contra-indicated from the fact that in large doses it is capable of producing gastric and intestinal irritation, and may even cause violent purging, vomiting, and in rare cases causes hemorrhage from the bowels and kidneys. This is however the result of enormous doses, and we should not entirely discard so important a remedy on account of its power of producing alarming symptoms when recklessly employed. It is true that in large therapeutic doses it decreases the excretion of urea and uric acid from the blood, yet I am of the opinion that when administered in *small* doses, 3 to 5 grs. every 6 hours, it is of decided advantage in combating the underlying cause of this malady, which is undoubtedly the much-dreaded malarial poison.

Now, as to the general principles of treatment, the patient should be comfortably clothed and all possible care taken to prevent his taking "cold" (as the laity say); he should be kept in a house where an equable temperature could be maintained, and any considerable amount of company should be excluded from the sick-room; and here let me state, that if we could adopt the plan more fully of isolation of the sick, I am confident that we would see a marked improvement in many of our cases. All excitement should be avoided as far as possible, and the patient should be kept as quiet as practicable.

Now, as to the diet, there may or may not be anorexia; in the former case, milk, or beef-tea, or gruels should be given in combination with whisky, or some of the astringent wines in small quantities and frequently repeated, and in all cases I am of the opinion that a liquid diet would be preferable to any other.

If the nausea and vomiting be so severe as to render all efforts at feeding per orem out of the question, it would be desirable to give the food per rectum, and to render it more easily assimilable, it would be well enough to add a small quantity of pepsin to the fluid just before injecting. And if the vital powers seem to be flagging, stimulants should be pushed, for it is astonishing to see how much these patients, on the verge of collapse, can take without displaying any symptoms of intoxication. If the patient's heart becomes weak, digitalis in small doses should be given.

After the establishment of convalescence the patient should be kept on nutritious food, but not allowed to indulge his appetite too freely, as they are wont to do; and I mention this from the fact that my case was, I think, unnecessarily prolonged by the attendant's well-meant theory—injudicious allowance of his cravings.

A tonic composed of tr. nucis vomicæ, ℥ss.; tr. ferri mur., ℥j.; glycerine, ℥ij.; aq. q. s., ad ℥vi.; M. sig., teaspoonful three times a day; and if heart is weak, tr. digitalis, ℥iij., added to above, answers admirably.

Case 1. Volley R., son of F. J. Roberson, who for the past eight or nine months has been living within a quarter of a mile of the

Ozan. He had been the subject at irregular intervals during the summer and fall months of paroxysms of intermittent fever, which had yielded to the salts of Peruvian bark; but when the anti-periodics were discontinued there would be a return of the paroxysms. For the four or five weeks previous to his last attack he had complained almost constantly of pain in his back and loins, and when a paroxysm came on he would experience a choking sensation, which caused him considerable discomfort.

On the morning of October 15, 1885, he had a slight chill, followed as usual by a febrile state of some hours' duration.

On the evening of the 16th at 1 or 2 o'clock he had another paroxysm, the delay in recurrence being attributed to the fact that he had taken during the forenoon several doses of quinine and a solution of liq. pot. arsenitis, gtt. j, ol. sassafras, gtt. j, spts. vini recti., gtt. xiv.

On the morning of the 17th he had a slight paroxysm and of short duration. On the evening of the same day he experienced a severe paroxysm followed by a very high fever, which lasted nearly all night, accompanied by delirium of a low muttering character, but when roused up and spoken to he seemed to be perfectly rational, and complained of a pain in his bowels, of a griping character, and of a feeling of fulness in the lower part of his abdomen, and of pain in the left hypochondriac and lumbar regions, a dull, heavy headache, persistent nausea and vomiting, and several evacuations from his bowels during the night, which were of a dark color.

Next morning, October 18th, about 7 o'clock, after an evacuation from his bowels and kidneys, the contents of the chamber was discovered by the attendants to be of a prune-juice color, indicating the presence of some abnormal constituent.

The family becoming very much alarmed, I was immediately summoned with the statement that he had hemorrhage from the bowels, and upon my arrival I found him complaining of very little pain except in the left hypochondriac and lumbar regions. Pulse 96, temperature 102½°. Skin hot and dry, and of a very deep yellow color. The icteroid condition of the conjunctiva was also well marked. There was extreme nausea, with frequent though ineffectual attempts at vomiting. The contents of the chamber were so intimately mixed that the urine could not be saved for chemical tests. They were of a deep prune-juice color. I ordered a combination of sodæ hyposulphite, acid gallic, fld. ext., ergot and tr. belladonna, to be given every 2 hours.

I saw him again at 11 a. m. of the same day, and found him very restless, saying that he "was very sleepy but could not sleep." Still an uneasy sensation in hypochondriac and lumbar region. Some pain in left supra-mammary region, which was attributed by the family to the frequent attempts at vomiting. Still considerable nausea and vomiting of a greenish-colored material. Respiration 20 per minute, and modified after the order of sighing. Pulse 100, temperature 103°. Had taken a small amount of milk. Nausea very troublesome and persists. He was given 30 grs. calomel and 2 grs. Dover's powder, to be repeated in four hours. The mixture heretofore alluded to was continued. At 3 p. m. he voided a quart of urine of the same prune-juice color, which was brought to me for examination. There was very little odor about it. Specific gravity 1022. Applying nitric acid, it yielded a very abundant white precipitate, which, after applying heat, showed at least one-half albumen. The precipitate removed, and more nitric acid added, failed to give a precipitate. Then adding a solution of nit. silver, the chlorides were found to be in excess. Equal parts of trs. guiac and turpentine added to a portion of urine gave a decided reaction in favor of the presence of blood.

Sunday night at 11:30. Respirations 24 and sighing. Pulse 120, small and very compressible. Temperature 97. Very restless and complaining of extreme nausea and frequent attempts at vomiting. He was given ¼ gr. morphia hypodermically, which quieted him down to some extent. At 12 m. Respiration 24 and more natural. Pulse 120. Temperature 98⅘.

Monday morning at 7 o'clock. Has had several evacuations from bowels during the night, which were of a very dark color and very offensive; no action from kidneys. Respiration 24 and sighing. Pulse 112 and very feeble. Temperature 97. Extreme nausea and frequent vomiting.

Monday at 12 m. Pulse 112, hardly perceptible at the wrist and very compressible. Respirations, sighing in character and somewhat faster than normal. Temperature 96. Nausea and vomiting still present to an alarming extent.

Monday evening at 6 o'clock. Respirations about the same as at 12 m. Pulse 120 and scarcely perceptible at the wrist. Temperature 95. Bowels been acting very freely all day; stools of an almost black color, staining articles green, and of a very offensive odor. Kidneys had acted once or twice dur-

ing the day, and were of the same color as on previous occasions. His features were pinched; nose and lips of a bluish-purple hue; skin still yellow, and every appearance indicating impending dissolution; could retain nothing on his stomach; he was given ¼ gr. sulph. morphia and $\frac{1}{20}$ gr. of sulph. strychnia, hypodermically, to be repeated in four hours, the dose of strychnia being decreased to $\frac{1}{30}$ of a grain. Enemata of milk and whisky every four hours.

Tuesday morning at 8 o'clock. Passed a moderately good night. Bowels acted several times during the night; stools still of a dark color and very repulsive. Respirations 24 and more natural. Pulse 112, with more volume than usual. Temperature 97⅖. There is still considerable nausea, though somewhat ameliorated as compared with previous evening. Strychnia and morphia continued per orem, and three-grain doses of quinine every three hours. Seen again at 11 a. m. Respirations 20, and very good. Pulse 112, and of good volume. Temperature 97⅖. Nausea still persists, but gradually abating; only complains when he takes medicine; says he feels better; there is still complete anorexia. At 8 p. m. Respirations 20. Pulse 100, and getting down to a good beat; temperature 97⅖. Nausea still present, though gradually subsiding; very little appetite; ordered milk and whisky per rectum.

Wednesday morning at 8 o'clock. Respirations 18, and normal in every respect. Pulse 80 and regular, with good volume. Temperature 97⅖. Says he feels better. Nausea not so severe as on previous evening. Consumed half a cup of coffee and half a soda cracker, which he retained. Strychnia, morphia, and quinine continued. Stimulants and nutriment ad libitum.

Wednesday evening at 3:40. Respirations normal in every respect. Pulse 80; good. Temperature 97⅖. Has micturated twice during the day, the urine on both occasions being free from blood. Nausea gradually giving way, having had only one or two attacks during the day. Has been eating a little. From general appearance, seems considerably improved.

Thursday morning at 7:25. Respiration normal. Pulse 84, of good volume. Temperature 97⅘. There is complete anorexia. Says he feels very weak, and complains of severe vertigo upon assuming the upright posture. Had an evacuation from bowels and kidneys, considerable nausea and slight vomiting following. There was about one pint of urine voided, of a light straw color; specific gravity of 1012, and contained no abnormal constituents nor excessive quantity of normal constituents discoverable by my limited resources for chemical tests.

Thursday evening at 5:25. Respirations normal; pulse 88, of good volume, regular; temperature 98⅘. Still weak and very irritable. Occasional slight nausea.

Friday morning at 8:20. Respiration normalin every respect, pulse 84, temperature 97⅖. Vomited at 7 o'clock, and complains of some nausea. Very little relish for food. Strychnia, morphia, and quinine continued, and iron in addition.

Friday evening at 5:40. Respiration normal, pulse 84 and tolerably full, temperature 99. Some slight tenderness in right iliac region. Bowels slightly tympanitic. No appetite.

Saturday morning at 11:20. Respiration good, pulse 82, temperature 98½. Anorexia still present. Was ordered in addition to the medicine above alluded to, milk and whisky every two hours.

Saturday evening. Respiration same as in morning, pulse 84, temperature 98½. Says he feels very well. Nausea about gone. General appearance very good. Some slight tenderness in right iliac fossa. Bowels very slightly tympanitic.

Sunday evening at 12:40. Pulse 82, full and regular, temperature 98. Bowels have not acted for two days and nights. He is restless and despondent, worrying about his bowels not acting. Ordered salts and an enema.

Sunday evening at 2:40. Pulse 82, temperature 98⅕. Very restless. Had a small action from bowels. An enema was given, and in 2 or 3 hours he had a copious evacuation from bowels and was greatly relieved.

Monday morning at 7:40. Pulse 72, temperature 98. General appearance good. Icterus entirely gone. Has some appetite. Very little nausea and no vomiting.

Tuesday morning at 9 o'clock. Pulse 72, temperature 98⅘. Still improving, and to all appearances out of danger. He continued to improve till Thursday, when a new train of symptoms developed in the form of severe pain of an aching character beginning in the epigastrium and traveling upward to the infra-mammary region.

I saw him at 8 o'clock Thursday night. He had been taking camphor and tr. opium at intervals during the whole afternoon, without experiencing any relief of the pain. I ordered tr. assafœtida gtt. xx., tr. opii camph. ʒss., spts. ammonia arom. gtt. xx., aq. q. s., to be given every 2 hours. This gave temporary relief, but when he came out from

under the influence of the medicine, the attacks would return with the same severity. Thinking that in all probability it was of a neuralgic character, I ordered quinine in 5 gr. doses every 4 hours, and 20 drops muriated tr. of iron every 6 hours. But he kept suffering more or less severely at intervals.

I saw him again Friday night at 7 o'clock, and found his abdomen tympanitic and irregular contractions of the muscular fibres, with a good deal of tenderness in the epigastric region and complaining of a constant dull, aching pain in that region, and an occasional attack of severe pain radiating to the infra-mammary region. He was given a hypodermic of ¼ gr. morphia and 10 drops tr. belladonna, and he rested well till midnight, after which the pain and uneasiness returned, though less frequently than before.

Saturday morning I ordered opii ext. gr. ½, camphor gr. ij., quinine sulph., gr. j., saponis, q. s. M. Sig. One pill every 3 hours.

On Monday morning, November 2, he was comparatively easy. Pulse seemed to be about normal. Temperature in mouth 98⅕, in axilla 98⅖. The abdomen was slightly tympanitic, with some slight tenderness in the right iliac fossa. Gurgling could be heard over whole abdomen, which I attributed to the fact that he had had no evacuation from his bowels since the morning before, and had taken salts during the night till shortly before my arrival, at which time he had a loose action, which was very black and tolerably offensive. He was given a 5 gr. dose of quinine and 20 drop doses of muriated tr. iron, to be given every 4 hours. Pills of quinine, opium, and camphor to be continued instead of quinine, every 4 hours. And as typhoid fever was feared he was to have nothing but liquid diet and 3 drops of turpentine twice a day.

Monday evening his temperature was 99⅕. Bowels had moved at noon. Pulse good. Tympanitis not so marked as in forenoon. Only very slight tenderness in right iliac fossa, it requiring deep and firm pressure to cause any uneasiness. Was put on tr. nux vomica ʒij., tr. digitalis ʒij., tr. ferri mur. ʒss., glycerine ʒss., aq. ad. ʒiij.; teaspoonful every 6 hours. Some slight tenderness in right hypochondrium. Complains of a slight frontal headache, which was attributed to large doses of iron, and it was accordingly decreased to 15 drops. Ordered him to be sponged off with tepid water, to which a small amount of bicarb. soda was added.

Tuesday morning. Temperature was 99⅖. Pulse good and regular. Had perspired pretty freely during the night. Tympanitis less marked than on previous visit. Tenderness almost gone. Says he feels better, and has a good appetite. Craves solid food, but none allowed.

Tuesday evening. Temperature 99⅖. Pulse good. Says he feels better, and his general condition indicates the establishment of convalescence. Was allowed a small quantity of bread and milk. Tympanitis almost none. No tenderness over bowels. Medicine continued.

Wednesday morning, November 5. His temperature was 98⅘. Pulse good. Very little tympanitis. Does not complain of any tenderness on pressure. Appetite good, and craves solid food; allowed to have rice and bread, with milk. Treatment continued as above.

Wednesday evening. Temperature 99. Pulse good. General condition good. Skin clear, and of a good color and feel. No tympanitis nor tenderness of abdomen; has sat up a good deal during the day, and says that he is gaining strength rapidly. Has an avaricious appetite, but diet still somewhat restricted. There has been no suffering since Monday, and the case was dismissed, and he rapidly recovered without any untoward symptoms.

Case 2. Lizzie R., sister to the preceding case, aged six years, of rather slender build, blue eyes, light, sandy hair, and moderately fair complexioned, had been having chills for several months at irregular intervals. The paroxysms could be kept off by the free use of quinine, but would invariably return shortly after discontinuing the treatment.

On December 16, 1885, she ate a hearty breakfast, and seemed to be doing well (having had a chill on the previous day) till about eight o'clock, when she began to complain of feeling sleepy, and in a short while she had a tolerably severe chill (though not so severe as the one on the previous day), accompanied with pain in her head, cramping pains in stomach and bowels, and a feeling of soreness across her loins. Just as her fever began to rise, or about an hour after the chill, she discharged about a half pint of urine of a bright red color. Fever ran right high. No nausea nor vomiting. I was sent for that morning, but being absent, my stepfather, Dr. Roberson, sent the following, to wit.:

℞. Hydrarg. chloridi mite, gr. xv.
Pulv. Doveri, gr. vj. M.

Dv. cht., No. 3. Sig.—One cht. every two or three hours. Also a combination of ergot, tur-

pentine, and sweet spirits nitre every three hours.

I arrived at the house that evening at about seven o'clock, and found the patient comparatively easy. Skin of entire body of a tolerably deep yellow color and boggy feel. Pulse 114. Temperature not taken, as I had failed to carry my thermometer; but roughly stated, I would say that it would not have exceeded 101° F. She was complaining of nausea, though there had been no vomiting. Bowels had acted once during the day; kidneys had acted seven or eight times. There being no change in the color from the bright red, I ordered—

℞. Strychniæ sulph., gr. ij,
Morphiæ sulph., gr. vj.
Aq. dest., ℥j. M.
Sig.—Ten drops every four hours.

Also,

℞. Fld. ext. ergot, ℥j.
Spts. etheris nit., ℥iij.
Spt. terebinth, ℥j.
Aq. q. s., ad ℥iij. M.
Sig.—Six teaspoonful every two hours.

Three-grain doses quinine sulph. every six hours, and stimulants and nourishment ad lib., were also ordered.

Thursday morning, at 8:40. Pulse 120; temperature 98. She had been troubled a good deal during the night with nausea and vomiting. Had had one action from the bowels and kidneys during the night. Urine not quite as deeply colored as before. Complete anorexia. Icterus still present.

Thursday, at 11 a. m. Nausea and vomiting still troublesome. I sent her five grains brom. pot. to be taken every two hours, which, as I had supposed from a theoretical standpoint, acted admirably, there being no recurrence of nausea after the second dose. I was told by her father that she was better in every other respect, the icterus being less marked, and her general appearance better.

Thursday evening, at 6:25. Pulse 120; temperature 100°. Bowels had acted several times during my absence. Kidneys had acted several times, and had been free from the coloring matter since the previous night. Had complained all morning of a feeling of soreness in her right side, though absent at my visit. Slight tenderness in right iliac fossa. Nausea had stopped at about two o'clock. The same treatment continued. General appearance was good; icterus gradually declining. I did not see her again, but she rapidly convalesced.

—A new caustic made of benzol and calomel, has proved useful in epithelioma.

Medical Societies.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Stated meeting, March 25, 1886. The president, Dr. J. C. Wilson, in the chair.

Recorder, Dr. W. E. Hughes.

Intracranial Hemorrhage.

Record and Classification of 143 *Consecutive Fatal Cases Observed in Medico-Legal Practice and in Private Autopsies in the City of Philadelphia, by Dr. H. F. Formad.*

Dr. Formad made some remarks on the different forms of intracranial hemorrhage he had observed, and presented a number of specimens in illustration. There existed, he said, no well-defined description of the various forms of intracranial hemorrhages with reference to their etiology, and no classification that could be of any service in medico-legal examinations, and Dr. F. suggested the classification and observations presented below as particularly adaptable for the latter purpose. These records may also be of some use to the surgeon who wishes to trephine. The observations were sufficiently numerous to warrant conclusions of importance for various ends. Dr. F. regretted that he met his cases on the autopsy table only, and hence was unable to offer clinical details. In some cases the history was far from being reliable, and in a few the history was left to conjecture from the surroundings, the circumstances of the case, and the appearances and general lesions of the body.

Dr. F. wished to give credit to his colleague in coroner's work, Dr. R. R. Stewart, whose assistance in these observations he enjoyed, and also to his assistants Drs. A. J. Plumer and George H. Chambers. Dr. Formad's cases of intracranial hemorrhage embrace the results of various kinds of head injuries (traumatic), and cerebral apoplexies (idiopathic hemorrhages) as well. By the term cerebral apoplexy, he meant exclusively hemorrhage in the brain, and did not refer to "congestive," "serous," "embolic," or "nervous" apoplexies and other affections, which tyrannic nomenclature has thrown together under the name of apoplexy. Idiopathic cerebral apoplexy should also be strictly separated from a traumatic cerebral hemorrhage (this is not done by many writers). The latter can be further subdivided into very well-defined sub-varieties of hemorrhages; each etiologically distinct, as will be shown below. These observations will clearly show the necessity and useful-

ness of a classification such as suggested. There should never be any reasonable doubt at the post-mortem table as to whether a cerebral hemorrhage was due to disease or to injury, or to both combined; nor as to whether a head injury preceded or followed an intracranial hemorrhage. Dr. F. believed that the diagnosis between the conditions just stated was much more difficult during life. He had seen errors made by the foremost surgeons and physicians, and in the best hospitals in this city. Dr. F. had seen cases of apoplexy diagnosed fracture and trephined, and he had seen cases of fracture of skull, unrecognized and untouched, left to die in the medical wards.

Upon the post-mortem table, however, there should be no difficulty in diagnosing such lesions at the present status of morbid anatomy as a distinct and well-defined science. After sufficient accurate observations have been made, and after seeing conditions repeat themselves, case after case alike, and having in the majority of instances cause and effect directly before the eyes, one should be enabled in disputed cases to make a post-mortem diagnosis which leaves but little room for doubt.

Dr. Formad divided the cases of intracranial hemorrhage observed by himself into the following eight different classes, the accounts being given here in abstracted form:

CLASS I.—12 CASES.

Post-mortem Appearance.—One or more small hemorrhage in the fasculi teres in fourth ventricle; also ecchymoses in the lining of the other ventricles; no massive hemorrhage anywhere; cerebral substance as well as membranes intensely congested. Cranium much congested; drops of blood oozing from cut surface and from periosteum all over. Mark of contusion in scalp, with more or less ecchymoses noted in all cases.

Histories.—In two cases death was caused by electricity (details will be recorded elsewhere). Ten cases revealed histories of concussion of brain from injuries to head, without fracture of skull. Death was rapid or sudden from shock in all these cases. Six were males and six females; the majority were young persons.

CLASS II.—23 CASES.

Post-mortem Appearance.—Massive hemorrhage (blood-clot) of various sizes found between pia and dura mater, location in the majority of cases about opposite to place of application of violence. In none of these cases was this meningeal blood-clot located immediately beneath the point of application of violence. Ventricular ecchymoses also found usually. Brain anæmic in the majority of cases, wherever hemorrhage is large. Scalp injury well marked in some, in others less so, while in a few cases it was hardly noticeable.

Histories.—Concussion from injuries to head without fracture in twenty-one cases; with fracture of skull in two cases. Death rapid (all within one hour) or sudden, either from shock or from compression of brain, the result of pressure from clot, or from both. Fourteen males; nine females; ages varied.

CLASS III.—45 CASES.

Post-mortem Appearance.—Massive hemorrhage (blood-clot) usually quite large, located between dura mater and inner surface of fractured skull, and at the site of application of violence only. Brain anæmic.

Histories in all these cases revealed injuries to skull from accidents, blows, or other violence resulting in fracture of skull. Death, on the average, ensued slowly from compression or anæmia of brain in the lapse of from several hours to several days (in a few cases, from five to eight days). Thirty-eight males and seven females; majority young and middle-aged persons.

CLASS IV.—12 CASES.

Post-mortem Appearance.—Massive hemorrhage, the same as in the preceding class, but occurring both at site, at application of violence, and also on some point on the opposite of skull; the first, a large clot between dura mater and skull, while the latter usually a small one, in the arachnoid (between dura and pia mater). At the site of injury there was found a fracture of the skull in all these cases, so that they presented the combined features of Classes II. and III.

Histories.—In these twelve cases there was shown injury to skull, resulting in both fracture and concussion.

Death was nearly instantaneous in all these cases. Nine were males and three were females, mostly young and middle-aged persons.

CLASS V.—9 CASES.

Post-mortem Appearance.—Punctiform and multiple hemorrhages into the tissue of the dura mater, which showed much thickening and adhesions to inner surface of skull from chronic pachymeningitis. Great œdema of the pia mater. Brain congested.

Histories in these cases revealed former attacks of sunstroke or old injury of head. Death usually sudden, and usually following

a fall or severe intoxication and excitement. Ages of deceased between twenty and fifty; all males.

CLASS VI.—34 CASES.

Massive hemorrhage of various sizes into the brain substance proper, and thence into one or both of the lateral ventricles. Hemorrhagic softening of brain substance of corpora striata or their vicinity. No meningeal hemorrhage in any of these cases, though in some instances blood was observed to have leaked out from the inner ventricles through the transverse fissure and the fourth ventricle, and some usually liquid (post-mortem) blood would be seen on periphery of brain in the meshes of the pia mater and arachnoid. Brain substance in nearly all cases quite anæmic. Atheroma of cerebral vessels in all but three cases. Multiple small aneurisms of cerebral vessels noted in several cases. Chronic pachymeningitis in various degrees in all but five cases. In some cases there were scalp injuries from secondary falls, *i. e.*, falls that were the result of a preceding cerebral hemorrhage. Many of these cases came under coroners' jurisdiction on account of suspicion of violence.

Histories, whenever obtainable, revealed either alcoholism, rheumatism, or syphilis. Middle or advanced age; 26 males, 8 females. Death in the majority of cases ensued slowly. These are true cases of idiopathic cerebral apoplexy.

CLASS VII.—6 CASES.

Post-mortem Appearance.—Massive hemorrhage of various size below pia mater, into brain substance, without breaking into lateral ventricles. In one case the blood clot involved the substance of the pons and protruded into fourth ventricle; in two cases it occupied the substances of the right parietal lobe, which was the seat of an abscess. In three cases the hemorrhage was multiple in smaller foci, with localized hemorrhagic softening of periphery of the brain substance in various places. In three cases there was atheroma, and in the other three fatty erosions of the cerebral vessels. Chronic pachymeningitis in all cases. Brain substance congested.

Histories wore those of former head injuries, alcoholism, and probable syphilis. Death rapid, following intoxication or exertions. Age advanced in all these cases; five men, one woman. Foul play had been suspected in all these cases.

CLASS VIII.—2 CASES.

Post-mortem Appearance.—Massive meningeal hemorrhage below pia mater, combined with hemorrhage into ventricles; no visible hemorrhage into brain substance. Atheroma and multiple small aneurisms of vessels of pia and of choroid plexus. Ecchymosis of scalp.

Histories of accidental falls. No previous symptoms of cerebral disease had been noted. Intemperate habits, injury of head leading to rupture of the diseased vessels, evidently had preceded the cerebral hemorrhage. The persons were at work (washing) at the time, when nearly simultaneous with the concussion from the fall, death ensued. Both were women; ages 57 and 63 years.

REMARKS AND COMMENTS.

A number of cases of intra-cranial hemorrhage observed by Dr. F., he had excluded from the series above detailed. Several cases of compound comminuted fracture in which the skull, membranes, and brain were partly pulpified into a mass, and hence the hemorrhage not being satisfactorily made out were excluded from the above records. He also excluded chronic cases of cerebral hemorrhage and those resulting in abscesses or in a fatal lepto-meningitis or cerebritis, after the patient had partly recovered from the immediate effects of the hemorrhage. Dr. F. did not incorporate into these records another large class of intra-cranial hemorrhage, viz: that of infantile meningeal hemorrhage. Of these he had seen many in coroner's work. Meningeal hemorrhage is common in infanticides and fœticides, and even in still-born children. Dr. F. could not plausibly explain the frequency of meningeal hemorrhage observed in the still-born, otherwise than presuming that they were due to traumatic injuries from violence or to compression of the cranium during protracted labor, or when forceps had been injudiciously applied. He did not meet with cerebral hemorrhage in children other than meningeal.

Returning to his classification, Dr. Formad stated that the quantity of the hemorrhage or the size of the clot in any case of intra-cranial hemorrhage appeared, in all the cases he observed, to depend upon the duration or the time that elapsed from the moment of injury to death. In cases where death ensued rapidly or instantaneously from shock, like in many fatal cases of concussion; or even in fractures of the skull followed by immediate death, like in falls from a great height, the bulk of the ante-mortem hemorrhage (the blood-clot) was remarkably small; or clots were occasionally entirely absent,

and only a post-mortem oozing of liquid blood could be observed. When death was protracted for several hours, then the blood-clot was usually large, weighing up to six or eight ounces, and causing death by compression of brain. In some cases of fracture of skull the hemorrhage is probably delayed for several hours, or ensues but very gradually. Some patients are said to have walked around for many hours after the injury, and subsequently when the blood oozed out in sufficient quantity to compress the brain, they fell, became unconscious, and died in coma. In one case of this nature he had found a meningeal clot weighing eight ounces.

Dr. F. observed that in the cases in which the intra-cranial hemorrhage was voluminous and death instantaneous, there was very little scalp ecchymosis; whereas scalp hemorrhage was more pronounced if the intra-cranial hemorrhage was small and death delayed.

Further, Dr. F. noticed that in no case where there was internal cerebral hemorrhage, was there any meningeal hemorrhage when cerebral vessels were normal; and in no case of traumatic meningeal hemorrhage did he see any coincident ventricular hemorrhage (except small ecchymoses) unless there existed some old lesion of the vessels or substance of brain. It appears, however, that blood from the lateral ventricles may leak through the foramen of Monroe into the third ventricle and thence by the acqueduct of Sylvius find its way into the fourth ventricle, but Dr. F. did not see in any one of the cases he observed that a primary hemorrhage into the fourth ventricle ever extended to the lateral ventricles, probably on account of its repeatedly fatal character.

A hemorrhage on the outside of an uninjured pia mater cannot reach the interior of the brain or the lateral ventricles.

The source of the hemorrhage is often very difficult to determine. In fracture of the skull the hemorrhage is often diploic; in concussion of brain the hemorrhage has for its source the vessels of the pia mater; in diseased conditions of the brain, or in atheroma of vessels, the small feeding branches of the middle cerebral and of the basilar artery bleed most frequently, and the blood breaking into the lateral ventricles forms clot in either one or both of the ventricles.

The view expressed by Dr. J. A. Lidell in his large treatise on apoplexy (N. Y., 1873, p. 113), that "meningeal hemorrhage not unfrequently occurs spontaneously, as well as in consequence of the operation of violent causes;" and that (see page 120) "meningeal hemorrhage of spontaneous origin is not a rare affection," is unquestionably erroneous. Yet such "views" are quoted by writers on forensic medicine and presented to juries in murder trials as FACTS. Ignorant or ill-informed post-mortem examiners can set murderers free; or, on the other hand, can create unnecessary court trials.

Conclusions:

1. Hemorrhages exclusively above the pia mater and above the dura matter, *i. e.*, on the outside of the brain, is always due to *traumatism* or to *sunstroke*, provided a cerebral source for hemorrhage is excluded and the cerebral vessels and membranes were not diseased.

2. Hemorrhage in the floor of the fourth ventricle is always traumatic, provided there are no blood clots in the lateral ventricles or any other part of the cerebral substance.

3. Hemorrhage exclusively below the pia mater, or in any part of the brain substance or in the ventricles (except the fourth) is always idiopathic, *i. e.*, is due to disease.

4. There must be a diseased condition of the cerebral vessels or substance in order to ascribe a hemorrhage to disease. There must be traumatism (a fall or a blow, etc.,) in order to account for a hemorrhage in a normal brain.

5. The blood clot in concussion of the brain is not found at the point of application of violence, but always somewhere about the opposite side of the brain, and always within the arachnoid, *i. e.*, between pia and dura mater.

6. The blood clot in fracture of skull is always found at the point of application of violence immediately below and always between the dura mater and the fractured part of the skull itself.

7. A blood clot formed within the cranial vault is more favorable to the patient if due to fractured skull than if due to a mere concussion.

8. Only clotted blood and infiltration of blood corpuscles into tissues indicate an ante-mortem hemorrhage; liquid blood is due to post-mortem oozing, and only stains, but does not infiltrate tissues.

9. Severe bruises and cuts of the scalp may be seen in cases of idiopathic apoplexy where a sudden cerebral hemorrhage causes a person to fall.

10. In some cases it is impossible to decide by medical examination alone as to whether a head injury and the resulting hemorrhage is due to a fall or to violence.

11. External marks of violence may be invisible to the unaided eye in some cases of injury of the head or other parts, but are easily detected and also distinguished from post-mortem spots by means of the microscrope (see above).

12. The bulk of an intra-cranial hemorrhage stands usually in inverse proportion to to that of the external scalp hemorrhage.

Dr. T. D. Dunn presented an unusual case of *cortical hemorrhage with rhythmical contractions of the left side of the body.* A widow, æt. 73 years, came under his care June 23, 1886, with the symptoms of congestive apoplexy. In a few days she recovered sufficiently to be able to leave her room. With the exception of some mental impairment for several months before the attack her health had been good. February 6 there was a second attack during the night, and when Dr. D. saw her there were regularly recurring movements of the left side of the body. Sensation and consciousness were not affected. The right side of the body could be moved at will, but articulation was impossible. The contents of bowels and bladder were discharged involuntarily. The movements continued during sleep. The movements gradually diminished, being lost in the leg on the fourth day and in the arm on the fifth. She died six days after the attack. At the autopsy a clot as large as a hen's egg was found situated on the right side of the brain very superficially extending from the ascending parietal convolution to be occipito-parietal fissure and from the convolution of the longitudinal fissure to the temporo-sphenoidal lobe. The convolutions pressed upon and partially destroyed were the ascending parietal, the convolution of the longitudinal fissure, the supra-marginal and the angular gyri.

Dr. F. A. Packard presented a patient having a *congenital anomaly of both hands.* The right hand consists of a thumb, an index and little finger, with only two metacarpal bones. The thumb has two phalanges and articulates with the same metacarpal bone as the index finger. The power of flexion is absent. The index finger has three phalanges. It can be flexed as a whole, but the individual phalanges are fixed. The little finger has three phalanges. The left hand consists of a thumb, index, ring, and little fingers with four corresponding metacarpal bones. The patient is one of five children. His mother and father are normally formed. One sister has one hand that resembles his left. Another has a left hand similar to his and on the right hand has the middle and ring fingers united throughout their length. One brother has both hands similar to this man's left. The only member of his generation not deformed is his twin brother. He has several children, all normally formed, and so, too, with his nephews and nieces.

Dr. J. M. Barton presented a *tumor of the stomach* removed from the body of a man æt. 47 years. His digestion became impaired two years ago, and soon afterward he noticed the tumor. The symptoms were mainly those of chronic gastritis, with at one time a profuse hemorrhage. The tumor was hard and well defined and occupied the epigastric region. At the autopsy the tumor was found occupying the upper portion of the pyloric outlet of the stomach and did not encroach enough on the outlet to prevent the ready passage of a finger. It was found on microscopic examination to be a scirrhous carcinoma.

CINCINNATI ACADEMY OF MEDICINE.

Stated meeting. May 18, 1886. Samuel Nickles, M. D., president, in the chair. G. A. Fackler, secretary.

Dr. E. G. Zinke reported

A Severe Case of Delirium Tremens.

The patient, æt. 33, clerk in a shoe store, had been addicted to the use of strong drink, especially whisky, for ten years. Had often been treated by the reporter for nervous attacks of a day or two in duration. This time he had been restless and without sleep for five days. Temperature 100; pulse 150, tremulous; appetite good; talkative and delirious. Prescribed—

℞	Chloral hydrat.,	drachm 2.
	Potass. brom.,	drachm 4.
	Codiæ sulph.,	grains 2.
	Syr. simpl.,	
	Aq. dest., āā	oz. iss.

M. S.—Tablespoonful every hour till asleep.

He took all this without procuring sleep. Requiring stimulants, he was put on ounce doses of whisky, with 30 drops of laudanum every three hours. Still no sleep. Delirium desperate. It required three or four men to hold him upon the bed. Fearing the opium and chloral, he was put on 30 grain doses of the bromide of potassium every two hours. He obtained no sleep, but grew worse. One-half grain morphia, subcutaneously, and the straight jacket were found necessary, and lastly, the administration of chloroform, which put him to sleep in about an hour. This, however, lasted but a short time. A

season of comparative quiet followed, but was succeeded by more violence than ever. The patient's appetite being good and his bowels regular, it was determined to again administer the chloroform. In large quantities this had some effect, and the patient improved. He was then put on chloral and did well.

Manifest prostration supervening he was given tablespoonful doses of wine of coca every four hours. From this time on recovery was uninterrupted.

The patient during the five days took the following amounts:

Bromide of potassium,	ounce 1.
Chloral,	drachms 3.
Morphia,	grains 3.
Laudanum,	drachms 5.
Chloroform,	ounces 20.

This seems a large amount of drugs, still the fact remains that he was little affected by them, and the reporter thought it required the combined effects of all of them to produce the desired result. He admitted he had used heroic treatment, but thought the case demanded it.

The sense of the discussion which followed was that food was of prime importance, bromide of potassium was the most suitable remedy, chloral and opium were dangerous unless handled with great care, and that chloroform was sometimes necessary as a dernier resort, but had not been needful in the hands of the speakers.

Dr. J. C. McMechan reported a case going to show the

Contagiousness of Phthisis,

and reviewed the literature on the subject. He complimented the work of the German Society for the Investigation of the Contagiousness of Disease under Meyerhoffer, and referred in extenso to the writings of Flint bearing on this subject. The essayist did not believe that the disease was contagious to any great extent, yet was to a limited degree. The case reported was one showing that the disease is contagious.

The gentlemen who took part in the discussion agreed fully with the essayist.

Dr. E. S. McKee reported a case of

Carcinoma Cervicis Uteri.

A German woman, æt. 40, came under his observation after nine months bleeding from the womb. She was very anæmic. Physical examination led to the diagnosis of advanced cancer of the cervix. She was given tr. ferri chloridi internally, and powdered chlorate of potash was applied to the cervix. Under this treatment she improved wonderfully, both as to her general and local condition. Indeed, this improvement was so marked that it was thought possible that it was not cancer but a case of extensive laceration with eversion, a very interesting point in differentiation. This, however, was soon dispelled. The hemorrhages returned with increased violence and the infiltration extended into the anterior vaginal wall, involving the bladder. She lived about seven months, when she was attacked by an acute peritonitis, to which she succumbed on the third day.

Post-mortem showed both ovaries degenerated and formed into numerous simple cysts, one of which had ruptured, causing peritonitis.

The Microbes of Pneumonia.

The *Lancet*, June 12, says:

The subject of acute pneumonia is one of those which of late has excited a considerable amount of attention, and yet, common as the disease is, it is one which is surrounded by many unsolved problems. Prof. Weichselbaum has recently contributed to the Vienna Medical Society a paper, in which, after stating the prevalent opinions upon the nature of the affection, and dwelling especially upon the different opinions held by Friedländer on the one hand and Fränkel on the other as to the precise characters and properties of the supposed bacterial agent, he relates his own experiences. He points out that clinicians are divided into two camps upon the etiological question, some regarding pneumonia as solely an infective disorder, others considering that the infective forms are different from those caused by exposure to cold. Weichselbaum, distinguishing between primary and secondary forms, divides them into:

1. Lobar.
2. Disseminated.
3. Passive pneumonia—hypostatic, etc.
4. Lobular.

He has examined 127 cases and instituted

eighty-seven cultivation experiments, the material for the cultures being obtained one or two hours after death, as well as from the living subject, by means of a Pravaz syringe introduced into the lung and pleura. He distinguishes four kinds of micro-organisms. The diplococcus pneumoniæ is the most common, consisting of oval, elliptical, and round cocci, which occur in chains as well as in pairs. The chains are composed of from six to eight or as many as twenty to thirty cocci, are straight or slightly curved, and the cocci are enveloped in a capsule of varying thickness in proportion to their vitality. The second variety resembles the first, but distinguished by a greater uniformity in spherical shape, and in forming long and sinuous chains. The third is known as the Staphylococcus aureus s. albus. The fourth he terms the bacillus pneumoniæ, consisting of rods of different lengths, the smallest and apparently youngest being oval. They have a capsule, and correspond to Friedländer's pneumo-coccus. The first variety was found in ninety-one cases, mostly of croupous pneumonia, also in the secondary forms. The second, or streptococcus, was found twenty times—namely, in fifteen cases of primary and five of secondary pneumonia. The staphylococcus only occurred in secondary cases, and mostly where the primary disease was due to this micro-organism. The fourth kind was met with nine times, four times unmixed with other forms. All these organisms were most abundant in the earlier stages of the disease, being scanty or absent in grey hepatization, and, if present, staining badly or unencapsuled. At the margins of the pneumonic focus in the œdematous tissue micrococci were numerous, pointing to the œdema being not a passive process, but a precursory stage of pneumonic infiltration, and resembling the invasion of cutaneous tissue in erysipelas. Moreover, inflammatory changes accompanied by these micro-organisms were found in the respiratory tract above the lungs. Secondary meningitis in pneumonia was shown to be due to the presence of the same micro-organisms, which were also found in the serous exudations of pleurisy and pericarditis, which might complicate the lung affection. The bacterial origin of the disease was therefore held to be demonstrated.

Effects of Various Drugs on Peptonization.

Dr. Klikovich has examined the effect of various drugs on artificial digestion, publishing an account of his observations in the Russian *Weekly Clinical Gazette*. His method was to determine the quantity of peptone after the action of artificial gastric juice for from four to six hours on dry egg-albumen and inspissated blood-serum. This estimation was made by the polarization instrument of Soleil and Wentzke, and by an instrument of Lorant's. For the preparation of the artificial gastric fluid, from 0.5 to 1.0 gramme of pepsine was added to a litre of water containing 10 cubic centimetres of officinal hydrochloric acid. For each observation from 20 to 40 grammes of albumen and 450 grammes of the digestive fluid were employed, 50 cubic centimetres of a solution of the drug whose action was to be examined being added, and a control experiment without the addition of the drug being arranged at the same time. In this way the following results were obtained: Alcohol, when less than 5 per cent. of the whole mixture, exercised no deterrent effect on the peptonization, 10 per cent. decidedly retarded it, and a still larger proportion arrested the process entirely. Antipyrin, in quantities up to 2.5 grammes, had no effect; larger quantities had only a slight retarding action. Iodide and bromide of potassium, only when in considerable quantities, interfered with peptonization; thus 0.5 gramme of the bromide had no effect, but 1 or 2 grammes showed a tendency to prevent it, the iodide acting rather more energetically in the same way. Organic salts of iron had no effect, but reduced iron and its inorganic salts exercised a decidedly adverse action on the process. Calomel, in quantities of from 0.3 to 1 gramme hindered peptonization, but not to a very great degree. Arsenite of sodium, when in quantities of from 0.05 to 0.1 gramme, did not appear to affect the process in any adverse manner; but from 2.5 to 5 grammes of salicylate of sodium produced a marked retarding effect. The sulphates of sodium and magnesium, even in small quantities, hindered peptonization. Chloral hydrate, in quantities below a gramme, had no decided effect; but when from 1 to 5 grammes were present a very marked effect was produced, and when more than 5 grammes were introduced the process was absolutely arrested. Chloride of sodium, in quantities of a gramme, had little or no influence. Acceleration of the process did not occur even with very small quantities, but with large ones a retarding effect was observed. Chloride of potassium gave similar results.

—Dr. D. Hayes Agnew's well-known works on surgery have been translated into the Japanese language.

Traumatic Tetanus Treated with Chloral Hydrate in Conjunction with Urethan—Recovery.

Dr. William Thomas Jackman thus writes in the *Lancet:*

The following brief notes of a case of tetanus which recovered under the influence of the new hypnotic, urethan, in conjunction with chloral hydrate, are of interest as suggesting a new use for this valuable drug.

J. C., a lad aged fifteen years, came under my care on March 15, 1886. The patient presented well-marked symptoms of tetanus, which were evidently the result of an injured finger on his right hand. This had been crushed by cogged wheels five weeks previously, and had healed up slowly under simple local treatment. The lockjaw was complete, and the opisthotonos well marked; severe paroxysms of pain were complained of, which were greatly exaggerated at night. The patient had noticed his neck and jaw muscles gradually becoming stiff for the past few days, but attributed this to a chill. Chloral hydrate in 20-grain doses every three hours was ordered. This relieved the paroxysms of pain slightly during the day, but the lock-law, opisthotonos, and rigidity of the muscles of the leg remained the same, and the pains were just as severe and frequent during the night. Fluid nourishment was administered and the chloral treatment continued until March 25, when, as no abatement of the symptoms was apparent, after consultation with my partner, Mr. T. Simpson, it was decided to discontinue the chloral during the night, and in its place give the patient four grains of urethan every two hours, from 6 p. m. to 6 a. m. The first night of this treatment showed a marked decrease in the severity of the symptoms, and the patient made gradual and uninterrupted progess until April 20, when his recovery was established. The failure of the chloral hydrate to relieve the severe symptoms during the nights, and the well-marked improvement under the influence of the urethan, seem to point to the latter being likely to prove a very valuable drug in the treatment of tetanus, either prescribed alone or as above in conjnnction with chloral hydrate.

Corrosive Sublimate as an Antiseptic.

This substance has come into very general use during the last few years, in the form of a solution, as an antiseptic. There can be no doubt that it possesses very considerable antiseptic powers; but, unfortunately, it is also a violent poison, and abundance of cases are now on record which show that its use is often attended with very great risk of toxic effects resulting from its absorption. In a paper recently contributed by Dr. Lucien Butte to the *Nouvelles Archives d' Obstétrique et de Gynécologie,* a long series of such cases is adduced, in many of which a fatal result followed persistent vaginal injections of the solution of Van Swieten (1 in 1,000). The symptoms of poisoning were the more difficult to detect from the fact that, occurring during the puerperal period, they were masked, to some extent, by those incidental to this state. They consist principally of hypogastric pain and tenderness, violent abdominal pain of a colicky character, accompanied by frequent mucous stools, often stained with blood. The urine is generally diminished in quantity, and contains epithelial cells, casts, and more or less albumen. Salivation is most frequently absent, but the mouth and throat are red and dry, and there is marked thirst. Dr. Butte is inclined to consider that absorption occurs most frequently in cases where lacerations of the perinæum, or of the cervix uteri, have taken place, or where large ulcerating surfaces are present. The toxic effects are naturally more marked in debilitated and cachectic patients. The post-mortem appearances are indicative of enteritis, with sloughing of the mucous membrane of the large intestine, while the kidneys are enlarged and anæmic. Deposits of crystals of oxalate of lime are common in the uriniferous tubules, due, it is suggested, to the decalcification of the bones, which is said to result from the presence of the bichloride in the system. As Dr. Butte quotes no fewer than twenty cases, in which the fatal result was attributable to absorption of the mercury, it is evident that, in obstetric practice at any rate, the use of even extremely dilute solutions requires very great caution.

Tubercle Bacilli in Addison's Disease.

It has long been held by some writers that the fibro-caseous change which characterizes the supra-renal bodies in Addison's disease is of tubercular nature, and the histological characters upon which this opinion rests have been strengthened by the detection of the bacillus tuberculosis in the morbid material. For this observation pathology is indebted to Herr Goldenblum, of Dorpat, in a well-marked case of the disease which he examined in 1884. The subject was a man twenty-four years of age; there was well-marked bronzing of the skin and mucous

membranes, caseation of both supra-renals, general wasting, pulmonary emphysema, cloudy swelling of the heart fibres, liver, and kidneys, and swelling of the intestinal solitary glands and the portal lymphatic glands. At Professor Thoma's suggestion the diseased capsules were examined by Ehrlich's method, and large quantities of tubercle bacilli found in the caseous masses (Virchow's *Archiv.*, Bd. 104, s. 393). Although Guttmann in 1885, and Rauschenbach in the present year, have reported cases of supra-renal bacillary tuberculosis, yet in neither case were symptoms of Addison's disease prominent, and both these cases must yield priority to Goldenblum's. He remarks that on the bacillary test his case goes to prove that in Addison's disease, in which the capsules are the only organs that exhibit caseation, the lesion must be regarded as a local tuberculosis, unless it can be proved that the occurrence of the bacilli is a secondary event.

Dr. Javal on Glaucoma.

The Paris correspondent of the *Lancet* (June 19) says that Dr. Javal, the well-known ophthalmologist and director of the Ophthalmological Laboratory of the Sorbonne, recently delivered a very interesting lecture on glaucoma, which he considers to be one of the most difficult subjects in ophthalmology. The lecturer chose this subject to demonstrate the fallacies that prevail even among specialists concerning the etiology and pathology of this affection. He remarked that the premonitory signs and symptoms are of little or no value as a means of diagnosis, as the same may be found in other affections of the eye. Even the ophthalmoscope does not render much assistance, as the excavation of the optic nerve is only produced at a later stage, and the pulsation of the central artery of the retina may be missing in glaucoma, and it has been seen in healthy eyes. And yet it is of importance that glaucoma should be early recognized and properly treated, as any error in diagnosis or treatment will inevitably lead to the most disastrous results. It is now known that expectant treatment is not permitted in glaucoma, and it is also known that the instillation of a single drop of atropine might produce irremediable mischief in an eye affected with glaucomatous prodroma. Even cocaine, notwithstanding the diminution of the compression which habitually follows its employment, might produce, in glaucomatous eyes, effects as baneful as those produced by atropine. When an eye feels hard to the touch and is accompanied with perikeratic injection, an immobile pupil and a rough and painful cornea, the diagnosis is easy enough; but it must be remembered that, in general, glaucoma sets in by alterations so futitive that no ophthalmoscopic sign reveals its existence. If, however, a patient complains of weakness of vision, and the surgeon observes the least inequality of the pupils, or the least paresis of the sphincter of the iris, Dr. Javal cautions against the instillation of atropine or cocaine, adding that an eye affected with glaucomatous prodroma is not always hard and may not present any abnormal appearance. The halo, however, observed by the patient is a sign by which a glaucoma may be known at its onset; but, as other affections may produce these halos, Dr. Javal recommends the instillation of eserine, and if the halos disappear under its influence the diagnosis is no more doubtful. As regards the treatment of glaucoma, Dr. Javal states that the same eserine will serve to combat the accidents of the commencement of the malady, and recommends it to be used in the form of gelatine tablets, instead of collyria, as being more convenient than the latter. If, after the application for a few days of the eserine, the symptoms are not completely arrested, surgical interference becomes absolutely necessary. But should an oculist not be within reach, and as every moment of delay is of importance, any medical man might afford temporary relief by making a slight incision of a few millimetres into the globe of the eye near its equator, between the internal recti and inferior recti muscles, as recommended by M. Parinaud. This little operation will permit the patient to proceed to an oculist, who ought to perform iridectomy without delay, and set aside sclerotomy, which is a useless and dangerous operation in such cases.

A Case of Recurrent Proliferous Cyst in a Woman of Sixty-three; Ovariotomy Twice within Nine Months; Recovery.

Dr. R. J. Shepherd reports this case in the *Lancet* of June 9:

Elizabeth B., aged 63, was admitted on June 26, 1885, suffering from tumor of the abdomen, with a history of between two and three years' duration. She was otherwise in good health. Dr. W. Beech Johnston, having been called in, confirmed the diagnosis, and also the prognosis that the case would be likely to do well. On August 7, bichloride of methylene was given by Mr. V. A. Jaynes, and Dr. Shepherd, assisted by Dr. W. Beech

Johnston, Dr. Malpas, and Mr. W. Steer, performed ovariotomy with strict antiseptic precautions. The tumor consisted of two large cysts, each about the size of a cocoanut, and of a prodigious number of smaller cysts from the size of a pea to that of a goose's egg. The pedicle, of a good length, was tied with carbolized silk and dropped back. The operation was a very simple one; there was no difficulty, and no ligatures were required. The sutures were removed on the eighth day, and when next the dressings were removed the wound was healed. Severe tympanites occurred on the third day and gave rise to some anxiety, but the temperature did not rise. It was probably caused by reflex irritation from a tight suture, of which some misgivings had been felt, and it subsided on its removal. Otherwise convalescence was uninterrupted, and the patient grew quite fat.

Early this year it was plain that the woman was again the subject of ovarian tumor. She was urged to submit to its early removal, but refused till April 19, when she again underwent the operation of ovariotomy. The tumor was the counterpart of its predecessor, only smaller. The pedicle was longer and had become twisted on itself, so that it had to be untwisted four or five times before the ligature was placed around it. The operation was even easier than before. She never had a bad symptom, and is now well.

Treatment of Chronic Ulcers.

In the *Brit. Med. Jour.*, February, 1886, Mr. W. S. Low records a case of long-standing chronic ulcer, which he treated with much benefit to the patient. A man, aged 48, had suffered for twelve years from a very extensive ulceration of the right leg. There was almost one mass of broken surface on each side of the knee, on the back of the calf, and in the popliteal surface, even extending to the posterior surface of the thigh. The surfaces were deep, with raised hard edges. The discharge was very offensive. The whole surface was first attacked with a lotion of solution of bichloride of mercury (one drachm to eight ounces). This was syringed daily over the wound, the condition of which was quickly sweetened. As the dead tissues separated, there often was much hemorrhage. At first the wounds were only dressed with lint wrung out in the bichloride lotion, but later on the author dusted finely-powdered iodoform freely over the most painful spots. This gave great relief to the pain, and contributed immensely to the comfort of the patient. In using iodoform, it is necessary not to persist in its application too long, as granulations tend to break down after it has been used for a short time. Its application to an inflamed surface should be avoided as it tends to irritate. Much benefit was derived in this case from the use of a Martin's elastic bandage, which was applied over the dressings from the toes to the thigh. In about six weeks the ulcer completely healed, and the general health improved.

Hot Baths, Hot Packs, and Pilocarpine Compared.

Dr. Zelenetski, of St. Petersburg, in order to examine the comparative effects of hot baths, pilocarpine, and hot wet-sheet packing on nephritis, treated the same patients on different days by means of each of these methods, observing the effects on the temperature, pulse, etc. Fifty-seven observations were made on seven patients, who were as nearly as possible under identical conditions. Twenty-three baths, eighteen hypodermic injections of pilocarpine, and fifteen hot packs were given. The hot baths produced the greatest loss of weight, averaging 801 grammes, and the packing the least, averaging 94 grammes, pilocarpine producing effects of an intermediate character. Here the mean loss of weight was 514 grammes—306 by perspiration, and 208 by salivation. The temperature rose considerably after the baths, and even at the end of three hours was always above normal. The packing caused it to fall at first; but after an hour it rose, and returned to its original height within three hours. With pilocarpine it was reduced for two hours, and then rose to normal. The pulse corresponded to the temperature with the baths, but became slower with both packs and pilocarpine. The patients expressed themselves as feeling the most improvement after the baths; the pilocarpine causing complications, such as headache and nausea, and in one case vomiting and collapse.

Nephrectomy and Resection of Lung.

A man, aged forty-nine, received a wound in the left side of the chest between the ninth and tenth ribs on August 30, 1885. There was a hernial protrusion of the lung of the size of half a fist. Urine and blood flowed from the wound from the very first. Peritonitis developed and gradually became localized to the left flank. Inflammation of the protruded lung and phlegmon of the tissues around caused M. Demons to resect the pulmonary hernia by means of the thermo-

cautery and écraseur, eight days after the accident. Profuse offensive discharge, however, continuing, and the phlegmon not subsiding, M. Demons performed nephrectomy on September 26, twenty-seven days after the accident. A vertical incision being made in the lumbar region gave vent to a large quantity of offensive matter, when the fascia of the quadratus lumborum had been incised. Considerable hemorrhage followed the removal of the kidney; suppuration continued for two months, and did not cease till a large sphacelus of connective tissue had been expelled. The case is interesting from a practical surgical point of view; unusual complications no doubt presented themselves, but the question remains whether the entire removal of the kidney was called for.

Two-Horned Womb with Double Vagina.

In the *Meditz. Obozrenie*, No. 24, 1885, p. 1068, Dr. Maria O. Prujanskaia, of Moscow, records the case of a strong and healthy married lady, aged 24, who began to menstruate at 13, the catamenia coming every three weeks, lasting each time seven days, and being always profuse and painful. She had four pregnancies, the first of which ended at full term, but the labor was difficult and tedious, and the child weak and short-lived; a second labor came prematurely; the last two pregnancies were interrupted by abortion in the fourth and second months. No catamenia appeared during the first two pregnancies, while the last two were complicated by an almost incessant, though slight, hemorrhage. On examination, the author found a double two-horned uterus with two fully-developed cervices, the right being virginal, and smaller than the left one, which presented all the usual signs of past labors. The vagina was also divided into two parts by a septum which was thrown off from the anterior vaginal wall in its two lower thirds, and could be felt and seen through the vulva, in the shape of a high fleshy crest attached to the posterior wall of the vagina.

Removal of Deep-seated Tumors of the Neck.

In the *Lancet*, January, 1886, Mr. A. E. Barker records four cases in which he removed deep-seated tumors from the neck with success. All the tumors lay beneath the sterno-mastoid muscles, and in one case the scalenus anticus muscle and inguinal jugular vein were implicated, and had to be cut away with the growth. From the experience gained by these cases, the author does not consider that any injury occurs to the nerves of the neck if proper care be taken, nor does any trouble arise when it is necessary to ligature one of the large veins of the neck. All the wounds healed by first intention, and were dressed in accordance with strict antiseptic principles; the carbolic gauze, however, being replaced by salicylic wool, which allowed pressure to be equally applied when the wound was bandaged.

Reviews and Book Notices.

BOOK NOTICES.

A Treatise on Diseases of the Nervous System. By William A. Hammond, M. D., etc. Eighth edition. 8vo.; illustrated; pp. 945. New York, D. Appleton & Co., 1886.

The author of this work justly congratulates himself that the various previous editions which have been called for have received the approval of the profession beyond that ever given to any other work of like scope and objects published in any part of the world. In order to maintain the high character thus attributed to it by the best judges, he has subjected this edition to a thorough revision, and has added a new section treating of certain obscure diseases of the nervous system, as tetany, Thomsen's disease, miryachit, and kindred affections.

We need say little of the general merits of the work. The style is always clear, forcible, and to the point. The references to other writers indicate an ample and discriminating knowledge of the literature of the subject; while numerous illustrative cases are drawn from the extended experience of the author himself. The difficulties of diagnosis which are especially present in many diseased conditions of the nervous centres are greatly reduced by a perspicuous arrangement of the symptoms; and the treatment recommended is, as usual with Dr. Hammond, positive and definite. In all respects, we must place this treatise as the best in the language on the specialty to which it is devoted.

—An advertisement extolling the virtues of a new make of infant's feeding-bottle winds up as follows: "When the baby has done drinking, it must be unscrewed and laid in a cool place, say under a tap." Poor baby!

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

DIFFERENCE IN THE EFFECT OF ELECTRICAL AND GAS ILLUMINATION IN A THEATRE.

Probably the most important investigation this year has been made by Dr. Breslauer in Berlin. The question was to determine the difference, if any existed, between the effect of illumination by gas and that of electrical light on the air in a large crowded building (*Deutsch. Med. Zeit.*, January 21, 1886). For this purpose the Royal Theatre in Munich was selected, and the experiments were made with that thoroughness with which they are usually undertaken by German scientists.

The air was examined in the parquet, the gallery, and the centre of the latter; and observations were made while the house was full and when empty. The results were as follows: With electrical light and with gas the increase of temperature noted from beginning to end of play was—

	Electrical Light.	*Gas.*
In parquet	2.5	25.0.
In gallery	8.1	26.1.
Centre of gallery	9.3	26.7.

The percentage of carbolic acid per mille was:

	Electrical Light.	*Gas.*
In parquet	0.055.	3.926 (!)
In gallery	0.870.	3.151 (!)
Centre of gallery	1.178.	4.353 (!)

Under the effect of gas the percentage of carbonic acid increased, therefore, above the limits of safety from 1.81 to 3.35 per mille! Many other observations concerning the percentage of watery vapor, etc., were also made; but we simply mention their result, together with the investigator's resumé of the whole.

1. The air with electrical illumination does not reach in a theatre the former high temperature, a fact especially of advantage to those frequenting the gallery.

2. The air remains purer; it contains far less carbonic acid, and almost no smoke-particles.

3. There is no longer so much moisture added to the air as used to be the case with illumination by gas, and the less the percentage of moisture in a crowded room, the more agreeable will be the air to persons living in it, and the less favorable will be the conditions for the development and the propagation of pathogenic germs, especially if the moisture diminishes in the same ratio as the temperature sinks, always occurring under the effect of electrical light.

4. The quality of the air has become a far more uniform one in all parts of the house, while with illumination by gas the air be-

comes the hotter, the more moist, and the more impure, the higher situated the seats are.

For hygienic purposes in the same theatre another alteration has been made, viz., the substitution of more opaque glass for the globes of the electrical light. Though the illuminating power has diminished under its use from 20 to 25 per cent., the effect on the eyes is less injurious, as it produces a peculiar mellow light, very agreeable to the eyes.

RED CORPUSCLES IN PSEUDO-LEUCÆMIA.

Again and again the fact has been stated that in Hodgkin's disease no increase of the white corpuscles occurs, but only a great diminution in the number of the red corpuscles; but here and there cases are reported, which evince a great ignorance in this respect. The mistake may, however, be easily explained. A physician, when examining the blood from a patient suffering from pseudo-leucæmia, will be misled by the proportion of red and white corpuscles as appearing on the field. Whoever bases his judgment on this fact is bound to commit an error, for the red corpuscles are so greatly decreased in number in this disease that the field easily makes the impression, as if the white corpuscles were present in increased numbers, while such is the case but relatively. In this respect the practical rule for new experts in microscopical examinations is not without its value; the blood comes from a leucæmic patient only when at least twenty white corpuscles appear on the field. More certain it is to study their proportion in connection with their number, for whenever the number of red corpuscles has decidedly diminished without there being an increase of the white, the disease belongs to the great class of anæmic and pseudo-leucæmic maladies, and not to that of true leucæmia.

As an instance to the point, we will mention a case recently reported in the *Deutsch. Arch. f. Klin. Med.* (xxxvii. Heft. 1 and 2), by Dr. R. Geigel. It concerned a boy æt. 12, who showed all the usual symptoms of a typical case of Hodgkin's disease. When he first came in charge of Dr. G., an examination of the blood demonstrated a decided diminution of the red corpuscles, there being only 2,440,000 to every cmm. blood, but within seven weeks this decrease became enormous—1,130,000 per cmm. The white corpuscles were not augmented absolutely, only relatively in comparison to the lessened number of the red. The urine remained free from albumen during the whole course of the disease, though daily analyses were made and on some occasions the urine was twice daily examined. Death occurred after the appearance of hydrops and of continuous fever. The post-mortem proved it a typical case of pseudo-leucæmia. The spleen was greatly enlarged. On account of the rather severe and continuous gastric symptoms, the case had first been diagnosed by a former physician as one of dyspepsia.

The typical cases of this malady, where all the symptoms are present, not being very frequent, Geiger's case is of interest as corroborating the fact stated at the beginning of these lines, and the diagnostic point raised also is of importance, especially as regards prognosis; for while cases of true leucæmia are often amenable to treatment, no case of true Hodgkin's disease has yet been reported cured; the latter malady always ending fatally within eighteen months after its first phenomena have made their appearance.

A POOR SPECIMEN OF PERSONAL JOURNALISM

The New York *Medical Record* has been so clearly put in the wrong about the International Medical Congress, and feels so sore at being exposed as the organ of the New York clique who want to break down the barriers of legitimate medicine and admit consultations with all sorts of irregulars, that it takes refuge in the last and worst of all defenses—an unfounded personal attack on the senior editor of the MEDICAL AND SURGICAL REPORTER.

This is the small-souled way in which Dr. Shrady satisfies his spleen:

> Our learned and scholarly contemporary, the MEDICAL AND SURGICAL REPORTER, is a stalwart supporter of the Old Code. This is an excellent thing, and is another reason for admiring the sunset covers of our neighbor. We believe, ourselves, in all that is moral in the Old Code, and especially in the section which says, "it is also reprehensible for physicians to give certificates attesting the efficacy of patent or secret medicines, or in any way to promote the use of them." Yet we observe, with sorrow, that there regularly appears in the daily papers an advertisement of a certain proprietary "water," which is "the famous specific for the cure of Bright's disease," and is endorsed by D. G. Brinton, M. D., of Philadelphia. We beg our erring contemporary to set a better example.

Now, as Dr. Shrady well knows, nothing is more common than for the names of persons of some prominence in the profession to be thus used without their consent. At this writing, we have before us the advertisement of an unblushing gynecological "professor," who refers to Drs. Thomas and Lusk, of New York city, as his guarantors. To come out

in a medical journal and accuse these gentlemen of connivance and approval of such reference would be disreputable and indecent in the person who did so. And we apply these adjectives to Dr. Shrady's action in the case quoted. We defy him to bring any evidence to show that the sellers of the proprietary water in question had any authority to use the name of the senior editor of this journal. They acknowledge in letters before us that they can produce none, and if Dr. Shrady had made the slightest inquiry before publishing his contemptible charge, he could have convinced himself of this. It shows to what poor straits a defeated man of a certain character may be reduced in order to seek revenge when he can no longer expect success.

Notes and Comments.

A Peculiar Pathogenic Cause.

In the Autumn of 1884, a coachman in Russia, who had been in the habit for years of sleeping with his horses on the straw or in the hayloft, and had occasionally been drinking with them out of the same trough, was seized with pains in the left chest. In October, several abscesses formed below the left mamma. They gradually increased in number, and changed to ulcers.

In August, 1885, he was admitted into the Jewish hospital at Berlin, and there came under charge of Dr. J. Israel, who reports the case in the *Centrlbl. f. d. Med. Wissensch.*, May 1, 1886. The patient then was greatly emaciated, and his left thorax was decidedly shrunken. The latter was covered with abscesses and ulcers, whose secretion contained many stellated fungi. These are also continually present in the sputa, which, usually muco-purulent, occasionally is tinged with blood.

In March of this year the patient died, evidently of complete exhaustion, superinduced by incessant diarrhœa, which yielded to no treatment.

The autopsy revealed as the only focus in the left lung a cavity situated in the lower part of the upper lobe immediately beneath the upper surface. The process of aktinomykotic degeneration had spread from the torn and irregular anterior wall of this cavity through the thickened pleuræ to the peripleural tissues, and penetrated the wall of the thorax at numerous points. The liver, spleen, and intestinal mucous membrane were in a state of amyloid degeneration.

In the aktinomykotic cavity of the lung a foreign body was found, which was of the size of a split pea, resembled, macroscopically, a piece of tooth, and was proved such by its microscopical and chemical examination!

Thus, for the first time, evidence has been adduced in favor of the hypothesis made by Israel, that the lung-aktinomykosis is caused by the aspiration of germs from the buccal cavity, and that at times carious teeth form the breeding place of these microorganisms.

The pathological specimens were presented to the Fifteenth Congress of German Surgeons, and a detailed report of the whole will be published in the annals of the latter.

Vicarious Menstruation.

There seems to be considerable diversity of opinion as to whether there really is such a thing as vicarious menstruation. That so high an authority as Dr. Robert Barnes believes in it is evidenced by his remarks in the London *Med. Press* (May 5), where he says:

"If then menstruation is not carried out in the ordinary way by the discharge of blood from the uterus, an attempt more or less successful will be made—

"1. By ectopic discharges of blood.

"2. By discharge of mucous serum, by leucorrhœa or diarrhœa.

"3. Or the material in the circulation, and the nervous energy prepared, will be used up in the other functions, as in the processes of gestation or lactation.

"4. By building up new tissues, as fat or other aberrant forms of metabolism.

"5. By effusions in the connective tissue, in serous cavities, or in the substance of organs.

"6. By exciting various neuroses, as hysteria, epilepsy, apoplexy.

"One of the most common routes chosen for vicarious menstruation is the stomach. In a large proportion of cases there is hæmatemesis simply, and in a further number there is hæmatemesis complicated by hemorrhagic discharges from other structures. Another common route is by the nose."

And he concludes thus:

"That as menstruation is a physiological necessity, so when the function cannot be performed in the ordinary way, some substitute for it must be found, or mischief will ensue.

"Vicarious or supplementary functional action is a fundamental law in physiology.

"There is nothing exceptional in vicarious menstruation.

"Vicarious menstruation may occur under many phases.

"It is conservative in intent and action, lessening or averting evil."

The Mitral Cardiac Murmurs.

The study of the mitral cardiac murmurs at the present time is of importance to every medical practitioner, as well as of interest to those whose attention is especially directed to the diseases of the heart. In an able article in the January number of the *American Journal of the Medical Sciences*, Dr. Austin Flint reviews our existing knowledge of these murmurs. He holds that there are four mitral murmurs, namely, (1) the systolic regurgitant, (2) the systolic non-regurgitant or intraventricular, (3) the presystolic, and (4) the diastolic. Each of these four murmurs has distinctive characters which individualize it. Two, three, and even all four, may be combined in the same case. This statement, as will be seen, applies to the systolic regurgitant and to non-regurgitant murmurs. The names post-diastolic and post-systolic, proposed by Hayden, seem to the author unnecessary refinements, and therefore objectionable. If the reader would stop to reflect upon the inquiry whether the mitral murmurs offer topics for consideration and discussion of sufficient interest and importance to occupy the thirteen and one-half pages which Dr. Flint devotes to them, let him refer to that portion of the elaborate and able work on diseases of the heart, by Hayden, which treats of the cardiac murmurs. He will there find a statement of the defects in our existing knowledge, together with differences of opinion in regard to the number of the mitral murmurs, their characters, their significance, and the modes of their production, which must convince him that they afford scope for an article extended much beyond the limits to which the author restricts himself. In fact, the object of the article is to present certain conclusions and suggestions, without attempting to consider the subject comprehensively and fully.

Eclampsia.

In an interesting article in the *Berl. klin. Wochensch.*, 1886, No. 21, Dr. H. D. Lewandowsky remarks, that even in those forms of eclampsia infantum not depending upon central nervous changes, one-sided spasms frequently occur, and that the only exception to this rule is met with in the very young infants still nourished by the breast. The convulsions begin, as L. had often occasion to convince himself, first in the face, afterwards the arm, and finally the leg on the same side are attacked. L. found all reflex excitability extinguished on the affected side in the pauses between the spasms. According to L., all the phenomena may best be explained by supposing an irritation of the motor centre of the cortex of the crossed hemisphere. L. considers chloroform the most effectual remedy for the convulsions. He also is of the opinion that the prognosis of these one-sided spasms is always a favorable one, and it is mainly in this respect that his observations are of great importance.

Heretofore, all one-sided convulsive movements were thought to depend upon structural central lesions, and their prognosis was accordingly looked upon as a grave one. But if L.'s investigations are correct, a fact which can scarcely be doubted, these one-sided spasms in children, if of an eclamptic nature, admit of a far more favorable prognosis than those attacking the whole muscular system.

Case of Ileus Cured the Seventh Day by Laparotomy.

Amongst the reports in the *Berlin Charité Annals*, x., p. 486, the following interesting case is told by Dr. Roehler:

A young man, æt. 23, after two attacks of perityphlitis, frequently suffered from spasmodic pains. After an immoderate use of fruit one day, intense pains again set in, accompanied by vomiting of green masses; after that, no movement of the bowels any more. The usual internal remedies and injections had no effect; from the fifth day the vomited matter assumed a fæcal character. In consideration of the preceding inflammation, the physicians supposed that peritoneal bands had strangulated the bowels. The seventh day an incision was made in the linea alba and the abdomen laid open. The fact that the tense bowels did not prolapse but remained fixed at once, was an evidence of the correctness of the diagnosis. The seat of occlusion was soon found; a band two inches long and three-quarters of an inch wide passed from one bowel to another, and a third was strangulated between them. While separating the adhesions, the bowel tore in one part, so that some excrement escaped. But the opening was successfully closed by Lembert's suture, and the abdominal wound was then closed with great care. Twenty-four hours later, the first motion of the bowels occurred, and the third day all vomiting ceased. The further progress of convalescence was undisturbed.

Intra-pulmonary Injections in Phthisis.

Whether or no this method of treatment has any merit to recommend it has been repeatedly discussed. To give all sides of the question, we reproduce the following conclusion of an article by Dr. John Blake White in the *Med. Record:*

To patients afflicted with this justly-dreaded affection, the intra-pulmonary treatment opens up new hope, and, I think, with good reason. The plan of treatment enables the physician no longer to stand with folded arms awaiting for his patient the inevitable end, but puts in his hands the means of prolonging and sometimes of saving life.

The following formula is the one which I have been using, and which seemed to occasion the least amount of irritability when injected:

℞. Atropia,	gr. ⅓.
Morph. sulph.,	gr. ij.
Tinct. iodine,	℥ iij.
Acid. carbol. (pure),	gtt. xx.
Glycerine,	℥ iss.
Diluted alcohol, 20 to 30 per cent.,	℥ iss.

M. Sig.—15 to 30 minims.

Rapid Dilatation of the Cervix Uteri for Dysmenorrhœa and Sterility.

Dr. A. H. Godet, of New York, thus concludes an article in the *Med. News*, April 3. The conclusions arrived at are:

First. That rapid dilatation is a perfectly safe, justifiable, and satisfactory procedure, free from the dangers which frequently follow the cutting operations, especially the occurrence of cicatricial contraction.

Second. If the stem be used in the after-treatment, recontraction does not occur, and the operation does not require repetition.

Third. The operation is demanded by the following conditions, viz.; (1) Marked stenosis, with or without flexion. (2) Acute flexion without actual stenosis, the obstruction existing only coincident with menstruation. (3) Slight stenosis, as shown by the passage of the sound, dysmenorrhœa and sterility existing without other cause. (4) Mild endometritis from acquired narrowing of the cervical canal and lack of free drainage for the discharges.

Modern Medicine of the English-Speaking Race.

In the opening article of the January number of the *American Journal of the Medical Sciences*, Sir Henry Acland presents a philosophical survey of the "Modern Medicine of the English-speaking Race," and referring to the new international character of the *Journal*, he says: "Some apology is offered to science for the assumption that there is room for a scientific journal with the apparent restriction to one language and one human stock. Science has no restriction and a universal brotherhood. But science has her votaries everywhere, and every language can contribute its share. The present endeavor is to offer to those who seek it, a means of hearing a message from English-speaking people, who, apart from politics of every kind, may gather results profitable to medicine, learnt from types of every climate of the globe, from very many races of the most diverse origin, and from every occupation and every condition in which the human family is engaged."

Items about Inebriates.

We take the following items from the *Quarterly Journal of Inebriety:*

Never contradict or attempt to reason with an intoxicated man; tell him clearly and kindly what you wish him to do, and then have power to compel obedience. This is an asylum axiom.

Sneers and denunciations of the disease of inebriety, and persecution of the facts are dangerous, for, like dynamite they will explode from pressure, and send their advocates into oblivion.

The defective memory of inebriates always leaves an impaired power to reason correctly as to the nature and character of acts, or to draw proper conclusions from the experience of the past.

The damage to the central brain regions in inebriety is clearly seen in the perverted sensations, so often manifested in hyperæsthetic and anæsthetic conditions of the skin, disorders of taste and the special senses.

Puerperal Aphasia.

Dr. Poupon, in the *Encéphale*, 1886, No. 3, reports the following case. A woman, æt. 24, four days after a normal delivery, was seized with right-sided hemiplegia and partial aphasia, probably produced by embolism of the left arter. fossa Sylvii, as the patient had been suffering for some time from regurgitation of the mitral valve. P. also mentions eleven similar cases in literature. Basing his deductions on these observations, he comes to the following results:

Aphasia in the puerperium is a very rare occurrence, and if happening, takes place the first few days after delivery. The aphasia may be produced by albuminuria, septicæmia,

transient disturbances of circulation (hyperæmia, anæmia of the brain), or permanent disturbances (hemorrhage, embolism, thrombosis). It may also depend upon nervous disturbances, hysteria, violent physical excitations. Its duration varies, twenty minutes, half hour, several days. Prognosis is favorable, especially for that form of aphasia due to nervous disturbances.

Poisoning by Ol. Succini.

A physically strong woman, æt. 30, had swallowed a tablespoonful of amber oil with the intention of committing suicide (Seybert, *Centrlbl. f. d. Med. Wiss.*, May 2, 1886). Immediately after she was seized with violent vomiting, scarcely controllable diarrhœa, and high temperature. She was pregnant, and the vagina showed a purulent discharge of not fœtid odor. Urine opaque, no albumen. The thirteenth day of her illness a twin abortion occurred, accompanied by moderate bleeding; both fœtuses were removed from the vagina in a very decomposed state. The next day one, twenty-four hours after, the other placenta was expelled. Symptoms of sepsis set in after the delivery, and in consequence of strong injections of corrosive sublimate, parotitis and stomatitis developed, but finally recovery took place. The disease in the beginning greatly resembled typhus. In the eastern provinces of Prussia ol. succini is employed as a popular remedy to bring about abortion.

Treatment of Furunculosis.

Guigeot (*Bull. de Therapeutique*) urges the adoption of a more rational treatment of boils than the old method of poultices, incisions, and bleedings, now that we have a more accurate knowledge of their pathology. The disease is inoculable (Lannelongue) and parasitic, the active agent being apparently the *torula pyogenica* (Pasteur and Löwenburg). The treatment must therefore consist of parasiticides as local applications. The acid nitrate of mercury and carbolic acid act well, but Guigeot prefers tincture of iodine, painted freely and repeatedly on and around the affected spots. If applied early it will abort the further development of the sore, and should be used prophylactically to any other synchronous lesions of the skin, to prevent them from becoming furuncular. For the face, camphorated alcohol may be substituted for the iodine, to avert discoloration. Internally he finds sulphur most useful, but its administration should be continued for a month at least, or even longer in obstinate cases.

Cocaine in the Vomiting of Pregnancy.

Weiss, of Prague, has used cocaine successfully in a case of vomiting of pregnancy which had resisted all other treatment. The patient was weak, anæmic, of a nervous disposition, and had suffered in three previous pregnancies from persistent vomiting; in the present pregnancy her condition was serious. One-twentieth of a grain of hydrochlorate of cocaine dissolved in alcohol and diluted with water was given every hour. After the sixth dose an improvement was noticed. After the sixteenth dose the patient ate with relish chicken broth, slices of white chicken meat, and drank a glass of wine without vomiting. The pulse and respiration increased in frequency, and the administration of the drug was interrupted for a time. Subsequently, hourly doses were given, with the result of checking the vomiting entirely.

Hypodermic Solution of Quinine.

Where it is necessary to administer quinine subcutaneously, the following formula is recommended by Dr. S. Burt as being as little irritating as possible:

℞.	Quiniæ bisulphatis,	ʒj.
	Acidi borici,	gr. ij.
	Morphinæ sulphatis,	gr. ¼.
	Aquæ distillatæ,	ʒj.

Sig.—For hypodermic use. One drachm contains seven and a half grains of quinine.

A Remedy for Coryza.

Rabow (*Deutsch. Med. Wochenschrift*, 5, 1886,) has repeatedly seen benefit from the following powders, used like ordinary tobacco snuff, which also they resemble in appearance:

1. Menthol, 2 parts; roasted coffee, 50 parts; white sugar, 50 parts: mix, and take as snuff.

2. Cocaine hydrochlorate, 1 part; roasted coffee and white sugar, of each 50 parts; mix, and use as before.

Cocaine in Labor.

It has been claimed by some that the local application of this drug will alleviate the sufferings of parturition. Five per cent. watery solutions have been applied on a tampon, through a speculum in the first, and without it in the second stage. While the results have been fairly satisfactory, it cannot yet be said that the use of this drug is as desirable as chloroform.

Disguising the Taste of Iodide of Potassium.

This remedy, which has a disagreeable and acrid taste, may be rendered comparatively palatable, according to one of our exchanges, by dispensing it in a syrup made from the juice of gooseberries.

Correspondence.

Cerebral and Spinal Trouble.

Eds. Med. and Surg. Reporter:

W. A. T., of Iowa, reports his case in the Reporter of May 15, page 640, and asks suggestions in reference to its diagnosis and treatment. He omitted to say whether or not his patient has had syphilis, or is or has been addicted to the use of alcoholic compounds. In consequence of this omission in the description, he has left his readers to diagnose the case as one of chronic inflammatory trouble or degeneration of the brain and spinal cord, which must be attributed to that depraved condition or diathesis of the general system, which is so often observed to excite a slow, tedious, and almost always fatal inflammation. The favorite organs of this morbid peculiarity of the constitution, are the lungs, kidneys, brain, and spinal cord, and when an inflammatory action is excited in either of these organs by the influence of a strumous state of the system, such cases are always serious, and a prognosis in reference to them must necessarily be unfavorable. If the brain or spinal cord is so attacked, entire recovery is the rare exception, and the rule is epilepsy, insanity, paralysis, and death, in a longer or shorter time.

The patient must avoid undue mental and physical exertion, and his bowels must be kept regular by the following tonic saline mixture:

℞.	Sulphate of magnesia,	℥iss.	
	Diluted sulphuric acid,	℥iss.	
	Tinct. gentian comp.,	℥j.	M.
	Aqua,	℥v.	

S.—Shake well. Dose a tablespoonful two or three times a day.

The application of three or four leeches to each temple, and the bites allowed to bleed for a few hours, will do much to relieve the pain in the head and the redness of the eyes. Mercury and iodine and their combinations, are the principal drugs to be relied upon in the attempt to cure the effect of strumous inflammatory action of the brain. The iodide of potassium, in the following combination, will probably make the best tonic and alterative:

℞.	Iodide of potassium,	℥ij.	
	Tinct. cinchona comp.,	℥vj.	
	Fluid ext. ergot,	℥iv.	
	Syrup. simplex,		
	Aqua,	āā ℥iij.	M.

S.—Shake well. Dose a tablespoonful after meals.

A very good formula in cases attended with epileptiform attacks is as follows:

℞.	Liquor hydrarg. bichlorid.,	℥ vj.
	Chloral hydrate,	℥ iss.
	Infusion gentian comp.,	℥ iv.
	Iodide potassium,	℥ ij.
	Syrup simplex,	℥ ij.

M. S.—Shake well. Dose, a tablespoonful after each meal for two weeks, and then an intermission of one week, unless the mercurial should make it necessary to drop its use earlier. In such an event, the balance of the formula may be continued with much advantage.

The diet should be bland and nutritious. Milk and water should be allowed as the only drinks. Tea and coffee or alcoholic compounds should not be allowed. Sleeplessness at night should be overcome by full doses at bedtime, of a combination of the bromides. If iron should be indicated, the syrup of iodide of iron is the best form in which it can be given in such cases.

The case which W. A. T. describes, is but a type of the many cases, which the physician meets in his practice, of troubles about the brain and spinal cord. The symptoms are slow and deceptive in their development. and often, long before they are decidedly pronounced, organic alterations have been sufficiently serious to preclude the possibility of the power of medicine to bring the brain to even an approximation of health. These cases have their remote cause in a scrofulous predisposition, and are most common between the ages of forty and sixty years. They are too often mistaken for dyspepsia and overwork, and the patient is too frequently injured by the administration of quinine, morphia or wine, and the various stimulating prescriptions for indigestion. Such cases are never relieved by a treatment suitable for dyspepsia, and they go steadily on from bad to worse. If the progress of a case is not suddenly ended by a fatal attack of apoplexy, other terminations are apt to take its place, and the listless manner, insane gaze, wild face, incoherent speech, palsied touch, altered hearing, halting step, and pitiful changed appearance of the whole exterior, tell that morbid manifestations have taken control of what was once the commanding activity of a healthy brain.

J. B. Johnson, M. D.

Washington City, D. C.

News and Miscellany.

A Turkish Confinement.

The following account of the accouchement of a Turkish princess, is from a private letter from Cairo, published in the *Albany Medical Annals:*

"Her highness had got a French nurse, so as to have the whole thing conducted on European principles. I was ushered into her presence by the pasha, her husband, the eunuchs stopping short at the bedroom door.

"The princess was unveiled, and lying on a mattress on the floor, being fanned by two Circassian slaves, who were seated on the floor at the princess' head.

"The princess speaks French fluently, so we communicated in that language rather than in Arabic, as I am ignorant of Turkish. I was not entirely a stranger to her, as I had superintended her taking gas some months ago when she was having a tooth extracted by her dentist.

"I told her it was very inconvenient for me to have her so very low down, so she got up and walked into another room where there was a bedstead, and in a few minutes I was told to come in. The pains were coming on about every ten minutes, but not severe, and not forcing pains. She inhaled the chloroform in right good earnest, so that three or four inspirations were sufficient for each pain. Between the pains she smoked cigarettes and talked. By and by the pasha brought in Dr. Fauzy Bey, one of the native surgeons at the government hospital. It seems the princess had seen him some time ago and asked him if he knew anything about giving chloroform in confinement cases, and, on admitting his ignorance, she told him that when she was confined it would be done under chloroform, and she invited him to come and see how it was done.

"He remained with me, therefore, till the accouchement was finished, and even had the hardihood to give the princess the last few whiffs of chloroform while I was supporting the perineum and conducting the child into the world.

"The princess was so thoroughly under the influence of the anæsthetic that she did not know when the child was delivered.

"Everything came off gloriously, and the child was a boy—a great consideration in the eyes of a Turk. I was with her six hours. As my custom is, I gave her a teaspoonful of ext. ergotæ liq. when the head was well down. It is now the fourth day since the event, and there has been no untoward symptom. She had no milk at her last confinement, and will have none now. There was a rise of about 2° F. after the accouchement, but that lasted only a short time. The lochia offered to stop entirely yesterday, so she has been up and about to-day, and brought it on again slightly. Altogether it is a most favorable case for introducing chloroform and medical men into the harems generally for confinements.

"Both the bandaging of the mother and the dressing of the baby seemed to be something quite new to them."

Chinese Medical Missions.

Unlike Japan, which has rapidly absorbed European medical and biological science, and is training men of first-rate knowledge and considerable original research, China is still in outer darkness. Chinese medicine is a by-word; Chinese surgery is almost non-existent; it is not surprising, therefore, to find that the Celestials are willing to take advantage to European skill, and attend the mission hospitals at Swatow and Ung-Kang-Phu in considerable numbers. The hospital arrangements for in-patients appear to be delightfully simple. "Scarcely a day passes," writes Dr. P. B. Cousland, in his annual report, "but little groups of, perhaps, husband and wife, mother and children, or a company of fellow villagers, may be seen coming into the hospital courtyard, with their baskets of the all-necessary rice, a few cooking utensils and bed-mats, and, perhaps, a mosquito-curtain, depositing them in a convenient corner until the janitor, or matron, has assigned to them their proper ward." Though there were 3,867 in-patients during the year, the only expenditure of the hospital in food seems to have been a sum of ninety dollars for "rice and cash tickets," so that the expenses are limited to the cost of drugs, and the wages of assistants and servants. The assistants, who do duty as house-surgeons and dispensers, are natives. The objection to submitting to amputation is very strong, and Dr. McPhun, in his report from Ung-Kang-Phu, where 2,620 patients were treated, complains that the majority of his patients were either incurably ill, or suffering from external diseases, because the Chinaman fears that internal remedies will work magically upon the heart to turn it from his ancestral religion. A very large proportion of the patients treated at the mission hospitals are suffering from diseases of the eye, the most common being trichiasis, and granular ophthalmia with its consequences. The number of opium-smokers treated at Swatow alone

was 649, but the prospect of permanent cure is not spoken of hopefully; many run away, unable to endure the misery of the first few days, and but few remain long enough to undergo a course of tonic treatment, which is considered to be essential.

Association of American Physicians.

At the first annual meeting of this new society held in Washington, June 17 and 18, the following papers were read:

"Chronic Catarrhal Gastritis," by Dr. Francis Delafield, of New York. "Tendon-Jerk and Muscle-Jerk in Disease, Especially with Reference to Posterior Sclerosis of the Spinal Cord," by Drs. S. Weir Mitchell, and Morris J. Lewis, of Philadelphia. "Typhoid Fever," by Dr. F. Peyre Porcher, of Charleston. "Spasm of the Glottis in Rickets," by Dr. James T. Whittaker, of Cincinnati. "Notes on Some Cases of Diaphragmatic Pleurisy," by Dr. Edward T. Bruen, of Philadelphia. "Demonstration of Bacterial Cultures from a Case of Mycotic Endocarditis in Man, and of Specimens Showing the Experimental Production of the Disease in Rabbits," by Dr. T. Mitchell Prudden, of New York. "Certain Elements Found in the Blood of Malarial Fever," by Dr. W. T. Councilman, of Baltimore. "Tetany," by Dr. H. M. Lyman, of Chicago. "Perforating Inflammation of the Vermiform Appendix; with Special Reference to Its Early Diagnosis and Treatment," by Dr. Reginald H. Fitz, of Boston. "Peri-uterine Inflammation," by Dr. William M. Polk, of New York. "An Experimental Study of Glomerulo-Nephritis," by Dr. W. H. Welch, of Baltimore. "Bicuspid Condition of the Semilunar Valves and Its Relation to Aortic Disease," by Dr. William Osler, of Philadelphia. "The Bacillus of Typhoid Fever," by Dr. George M. Sternberg. "A Clinical Report of Nine Cases of Hemianopsia," by Dr. E. C. Seguin, of New York.

The following papers were read by title: "Notes of a Case of Hepatico-Bronchial Fistula," by Dr. J. E. Graham, Toronto. "Pancreatic Hemorrhage as a Cause of Sudden Death," by Dr. F. W. Draper, of Boston. "Pernicious Anæmia," by Dr. A. Jacobi, of New York. "A Case of Hodgkin's Disease," by Dr. F. Forsheimer, of Cincinnati.

The following officers were elected for the ensuing year:

President.—Dr. S. Weir Mitchell, of Philadelphia.

Vice-Presidents.—Drs. Francis Minot, of Boston, and R. Palmer Howard, of Montreal.

Secretary.—Dr. George L. Peabody, of New York.

Recorder.—Dr. G. T. Whittaker, of Cincinnati.

Treasurer.—Dr. W. W. Johnston, of Washington.

Council.—Drs. Wm. F. Draper, of New York; Robert T. Edes, Boston; H. M. Lyman, of Chicago; Samuel C. Busey, Washington; Fred. C. Shattuck, of Boston; Wm. Osler, of Philadelphia; and W. A. Welch, of Baltimore.

Bowditch on Homœopathy.

Dr. Vincent T. Bowditch, late President of the Boylston Medical Society, has been addressing the Hahnemann Society of the Boston University School of Medicine on "Homœopathy as Viewed by a Member of the Massashusetts Medical Society," and he thus concludes his remarks (*Boston M. and S. Jour.*, June 30):

"Gentlemen, from the use of cant phrases and figures of speech which smack of a mawkish sentimentality, I shrink instinctively, and I sincerely wish I could express in new and simple words the thought to which I wish to give utterance before I bid you farewell, yet I feel sure you will receive it in the spirit I wish.

"We are *all* members of a profession which, when regarded in its true light, above the plane of party strife and mere selfish gain, I regard as the finest and noblest of all, and the feeling grows stronger within me with each year of practice. There is that in it far above the mere desire and ability to cure disease; that which can soothe all regrets for possible failure and disappointment in our daily work—I mean the power of human sympathy; the power which bids the young mother silently and gratefully press the hand that helped her in her hours of trial; the power that impels the dying man at the very last to turn to him who, though powerless to save, yet by a word, a look, a touch of the hand, gives strength and courage to one just passing to that 'undiscovered country from whose bourne no traveler returns.' In the midst of discord and disappointment, let us keep this thought before us gentlemen, and at the end perhaps we may be permitted to see our past life, as it were, stretched before us, and feel that we have done our small share towards making our chosen professson what it should be, 'a blessing to all mankind.'"

The Wonders of an Egg.

The *Popular Science News* says that Mr. Matthieu Williams, in one of his lectures, says: "Every one who eats his matutinal egg, eats a sermon and a miracle. Inside of that smooth, symmetrical, beautiful shell lurks a question which has been the Troy town for all the philosophers and scientists since Adam. Armed with the engines of war—the microscope, the scales, the offensive weapons of chemistry and reason—they have probed and weighed and experimented; and still the question is unsolved, the citadel unsacked. Professor Bokorny can tell you that albumen is composed of so many molecules of carbon and nitrogen and hydrogen, and can persuade you of the difference between active and passive albumen, and can show by wonderfully delicate experiments what the aldehydes have to do in the separation of gold, from his complicated solutions; but he can't tell you why from one egg comes a 'little rid hin,' and from another a bantam. You leave your little silver spoon an hour in your egg-cup, and it is coated with a compound of sulphur. Why is that sulphur there? Wonderful, that evolution should provide for the bones of the future hen! There is phosphorus also in that little microcosm; and the oxygen of the air, passing through the shell, unites with it, and the acid dissolves the shell, thus making good strong bones for the chick, and at the same time thinning the prison-walls. Chemists know a good deal now about albumen; and if they cannot tell us why life differentiates itself therein and thereby, they can tell you how not to spoil your breakfast."

Massachusetts State Medical Society.

At the 105th annual meeting, held in Boston, June 8 and 9, the following papers were read:

"Abuse of Medical Charity; a Remedy Applied in 3,000 Cases of Out-door Patients; Results," by Dr. Frederick F. Doggett, of Boston. "Does the Law Recently Enacted by the Legislature Prevent the Spread of Scarlet Fever?" by Dr. John L. Hildreth. "The Present Status of Bacterial Pathology and its Relation to Therapeutics," by Dr. Albert N. Blodgett, of Boston. "The Management of Cases of Rigidity of the Os Uteri in Labor," by Dr. William E. Boardman, of Boston. "A Not Well-recognized Source of Domestic Poisoning, with Cases," by Dr. Charles Harrington, of Boston. "Abdominal Cellulitis," by Dr. Julian A. Mead, of Watertown. "An Epidemic of Malaria in Eastern Massachusetts in 1885," by Dr. Zabdiel B. Adams, of Framingham. "The Causation and Treatment of Lateral Curvature," by Dr. Edward H. Bradford, of Boston. "Some of the Results of Fractures," by Dr. Joseph E. Garland, of Gloucester. "The Etiology and Treatment of Summer Diarrhœa of Infants," by Dr. Henry C. Haven, of Boston.

Extraordinary Medical Skill.

In *Harper's Magazine* for July we read that on a stormy night, when the roads were well-nigh impassable, a son of Erin came into a doctor's office and desired the dispenser of physic to go to see a friend who was "jist a-dyin'." He would not take no for an answer; so, putting the saddle-bags upon his horse, the physician started out upon his journey. As soon as he saw the sick man he knew it was nearly over with him, and remarked to the courier:

"Peter, you told the truth; your friend is just at the poiut of death."

"Can't ye do ainytheeng for heem?" replied Peter.

"No; it is too late."

"But, docthor, ain't ye goin' to give heem ainything at all at all?"

"It will do no good."

"But, docthor, ye have come so far, it would be too bad to go back without doin' ainything."

For the peace of Peter's mind, the doctor now took a small quantity of sugar from a phial, and placed it upon the dying man's tongue just as he was drawing his last breath.

Peter, seeing his friend's head drop back, looked up to the doctor with big eyes, and said, half in a whisper, "Oh, docthor, an' didn't ye do it quick!"

The Operating-Room of a Vienna Ophthalmologist.

Dr. G. H. Claiborne, Jr., writing from Vienna to the *Virginia Medical Monthly*, describes the operating-room of Prof. Hirschberg: "His operating-room is a model of scientific care and accuracy. The floor and tables are of marble; the walls are painted with an oily substance which allows of their being washed with soap and water. Glass and porcelain are the materials of which the basins for instruments and disinfecting fluids are composed. The hands of all parties concerned in the operations are washed with soap and water and bathed with a sublimate solution ($\frac{1}{1000}$). The instruments for operations on the ball lie in absolute alcohol;

those for muscle and lid operations in a three per cent. carbolic acid solution. Cocaine and atropine are dissolved in $\frac{1}{500}$ sublimate solutions, and a separate new bottle is used for each case. Prof. Hirschberg disinfects the conjunctiva by wiping it carefully with antiseptic gauze wet with a $\frac{1}{5000}$ sublimate solution, and instills one or two pipettefuls of the same solution over the wounds after the operations are finished. He never operates out of this room. Each patient has his own box of solutions, pencils, bandages, etc."

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE FIVE WEEKS ENDED JUNE 26, 1886.

Mead, F. W., passed assistant surgeon. Granted leave of absence for twenty days, June 9, 1886.

Guiteras, John, passed assistant surgeon. Granted leave of absence for thirty days, June 14, 1886.

Watkins, R. B., assistant surgeon. Granted leave of absence for thirty days, June 4, 1886.

Pettus, W. J., assistant surgeon. To proceed to Charleston, S. C., for temporary duty, June 11, 1886.

Sawtelle, H. W., surgeon. To proceed to Wilmington, California, on special duty, June 22, 1886.

Wheeler, W. A., passed assistant surgeon. Granted leave of absence for thirty days, June 23, 1886.

Williams, L. L., assistant surgeon. To proceed to Buffalo, N. Y., for temporary duty, June 24, 1886.

Norman, Seaton, assistant surgeon. To proceed to Cleveland, Ohio, for temporary duty, June 26, 1886.

A Troublesome Patient.

A foreign exchange tells us that an incident in professional life is reported from Vienna, in which a tailor, on being told by his physician, whom he had called to consult as to a disease from which he was suffering, that recovery was impossible, forthwith shot the physician in two places, and then turned his arm—or rather arms, for there were several—against himself, with a fatal result, so far as he was concerned. Nine shots in all were fired; and the number may, perhaps, be accounted for by the fact of this recalcitrant patient being a tailor; but it is to be hoped that a needless complication will not be introduced into professional life by such a practice becoming general. Medical men have already a good deal to put up with from patients; and, if further difficulties be introduced, the relations of doctor and patient may become strained. In any case, the medical man, if he must needs take lead, would probably prefer it in the shape of false coins to the more conical form of revolver bullets. We are glad to state that the physician was not much hurt, and will shortly be able to resume what may be considered an eventful career.

Salicin.

The willow is now being largely cultivated in America for medicinal purposes. The switches at the end of two years are from four to seven feet long, and are cut and gathered in bunches like sheaves of wheat. In the stripping building they are steeped in water, and the bark at the larger end is loosened for a couple of inches by machinery. One by one the switches are placed in a mechanical stripper, and with a pair of pliers are pulled through with a sudden jerk. They are then wiped off with a woollen cloth, bundled, and laid away to dry. All the leaves and bark are dried and baled, when they command a price of 25 cents a pound. On one farm in Georgia there are at present 400,000 willows growing, and 80,000 additional slips have recently been put in, it being intended eventually to devote sixty acres to this crop. The average yield is a ton to the acre. When dried, the willows command $200 per ton, and find a ready market.

How to Keep a Cistern Clean.

The *American Agriculturist* says that complaints are frequent of the impure water of cisterns. This is inevitable under the careless management of these useful additions to the water-supply, and is a fruitful source of what are called "malarial diseases." A roof gathers a large quantity of impure matter, dead insects, droppings of birds, dust, dead leaves, pollen from trees, etc., etc., all of which are washed into the cistern, unless some means are provided to prevent it. Even then the water should be filtered before it is used for culinary purposes. One way of preventing foul matter from entering the cistern, is to have the leader movable, and swing from a waste-pipe to the cistern pipe. In dry weather the pipe is turned over the waste, and after the rain has fallen for a sufficent time to wash off the roofs and gutters

it is turned into the cistern pipe. The cistern is provided with a soft brick wall laid in cement, through which the water filters, coming out by the pump perfectly pure, and free from unpleasant odors.

A Certain Cure for Corns.

The *Med. Press* tells us that a Berlin gentleman, very much troubled with corns, saw in a paper an advertisement for a certain cure for them, application, enclosing 1 mark 10 pf. in stamps, to be made under cover to A. X., Post Office, Geneva. The gentleman not unnaturally made application, and in the course of a few days received the following reply, which we have feebly striven to give in English:

Sind ihre Hühneraugen gross
So dass von Schmerz Sie schwitzen
So sägen Sie die Zehen los
An denen solche sitzen.

(Have you large corns upon your toes,
So that with pain you sweat, Sir?
Then take a saw and saw off those
On which your corns are set, Sir.)

"I recommend for this purpose my bone saws; price from 10 to 30 mark."

A Better Fee than Billroth's.

Dr. C. Beard (retired), late of New Orleans, now of Boston, writes to the *Med. Record*:

"Referring to your mention, in your last number, under 'News of the Week,' of the fee, 25,000 francs, to be received by Professor Billroth, of Vienna, for an operation to be performed upon a wealthy banker of Alexandria, Egypt, in 1858 I was paid a somewhat larger sum—$5,000—for a cataract operation on Mr. Lastie Duprée, of Opelousas, La., and did not leave my home. Judging from the unction with which the announcement is made abroad, the foreign estimate of the value of distinguished services, at the present day, must be at least no higher than it was in this country before the war, and fees paid to distinguished men much lower than they were, according to my recollection, when I was in Europe in 1849–52."

To Render Corks Ether-tight.

The *National Druggist* says that C. Neuman has recently pointed out that corks may be rendered ether-tight by chrome-gelatin. It is well known that ordinary corks very soon become porous to the vapors of ether, benzol, and other volatile liquids, which gradually carry off every trace of moisture. By coating the corks with a solution prepared from 4 parts of gelatin, 52 parts of boiling water, and 1 part of ammonium bichromate (added to the filtered gelatin solution), and then exposing them for a few days to sunlight, absolutely tight stoppers will be obtained. The apparatus may be put together with unprepared, sound corks, and the exposed portions of the latter afterwards coated and exposed to sunlight. It is well known that gelatin, in the presence of bichromates, is also rendered insoluble in water by exposure to light.

Temperance Drinks.

"Temperance drinks" have become very popular in England, but recent investigations show that the name is in some cases a misnomer. The *Popular Science News* says that at Birmingham a sample of "temperance port," warranted by the dealer as "unfermented and free from alcohol," was found on analysis to contain 17.4 per cent. of proof spirit; and a "temperance sherry," so-called, contained 19.6 per cent. No wonder that these "non-alcoholic" beverages become favorites with "reformed" tipplers, and, what is worse, that they tend to encourage tippling among people who use them without suspicion of their real nature. Several makers and sellers of these dangerous and delusive liquors have been detected, and prosecuted for violation of the excise laws; and it is believed that the illegal and demoralizing traffic will ere long be broken up.

Rhode Island Medical Society.

At the 75th annual meeting, recently held in Providence, the following officers were elected for the ensuing year:

President—Dr. Horace G. Miller.

Vice-Presidents—Dr. Albert Potter and Dr. John W. Mitchell.

Recording Secretary—Dr. George D. Hersey.

Corresponding Secretary—Dr. E. M. Harris.

Treasurer—Dr. Charles H. Leonard.

Board of Censors—Drs. A. Ballou, J. H. Eldredge, J. W. C. Ely, G. P. Baker, S. S. Keene, Benjamin Greene, Eugene Kingman, and Job Kenyon.

The Yellow Fever Commission.

The Washington correspondent of the *N. Y. Med. Jour.*, says that the Senate has passed the yellow fever commission bill, which was

urged in person by Dr. Joseph Holt, of New Orleans, in behalf of the American Public Health Association. Some opposition on the part of some of the friends of the late National Board of Health, and some sentiments of frugality, induced Congress to amend the bill so that it now provides for the detail of two officers already in the service, but with the proviso that they must be skilled in bacteriology and microscopical research. No provision is made in the bill for the appointment of a member of the commission from civil life, but the employment of experts is allowed.

A Higher Standard of Education.

The last report of the Illinois State Board of Health takes the ground that the diminution in the number of students and graduates in the medical colleges of the United States during the session of 1884–5 was due to a general and increasing desire on the part of the profession to raise the standard of attainments necessary to enter its ranks, and to the enforcement of certain requirements in States which have enacted laws regulating the practice of medicine. This seems a very probable explanation, and is sufficient to excite considerable reflection as to the causes at work which may influence medical education in this country.

Ferran's Laboratory.

A correspondent of the London *Times* writes that while Ferran was in Valencia he used for his laboratory the kitchen of a new and as yet uninhabited house. In this kitchen there was a water-closet, placed against the inner wall as far as possible from the windows, and ventilated into the kitchen through an opening over the door. The house had just been built by a physician of Valencia, who apparently had as much sense of the fitness of things as he had knowledge of sanitary science. The writer adds that the closet was already so foul and choked up that he was unable to discover whether it was trapped or not.

Indiana State Medical Society.

At the meeting of the Indiana State Medical Society, held at Indianapolis May 11 and 12, the following officers were elected for the present year:

President—G. W. H. Kemper, M. D., of Muncie.

Vice-President—W. V. Wiles, M. D., of Spencer.

Secretary—E. S. Elder, M. D., of Indianapolis.

Assistant Secretary—J. McLean Moulder, M. D., of Kokomo.

Treasurer—C. B. Higgins, M. D., of Peru.

Connecticut Medical Society.

At the 96th annual meeting, held at New Haven, May 26 and 27, the following papers were read:

"A Study of Diabetes Mellitus," by the president. "The Treatment of Lacerations of the Cervix Uteri," by Dr. Beckwith, of New Haven. "The Microscope in its Relation to Disease," by Dr. Wright. "O Tempora, O Mores!" by Dr. Stanton. "Morbus Brightii," by Dr. Wright. "Pneumonia," by Dr. Gilbert.

Items.

—It is proposed that the Medical Department of the Virginia State University be hereafter located in Wheeling.

—In the *Annals of Surgery*, for June, Dr. Robert T. Morris reports a case of amputation of the leg, with recovery, in a man eighty-three years of age.

—Dr. G. C. Savage, of Jackson, Tenn., has recently been elected Professor of Ophthalmology, Otology, and Laryngology in the Universities of Nashville and Vanderbilt.

—In remarking upon the saying by Carlyle that "Dyspepsia kills poetic ambition," the *Boston Post* says: "If dyspepsia would only get its work in more constantly, it would be for the comfort of the world generally."

—Before undertaking a post-mortem, Dr. Crevenger recommends holding the hands over strong liquid ammonia, when the smarting which ensues will reveal all sensitive or abraded places that need a touch of caustic before beginning the examination.

—"Here comes the mustard-plaster," said a shopman to another, as a lady with a sharp nose and a business-like air, waltzed into the shop and proceeded to tumble over a big pile of goods. "What a funny name!" said a customer who was standing by; "why do you call her a mustard-plaster?" "Simply because she gets in front of the counter and buys nothing, and asks so many questions that she irritates the poor man who is waiting on her." "How does that make her a mustard-plaster?" "Because she is a counter-irritant."

Pallas Syringe." The most useful Instrument for Vaginal Medication and Irrigation.

W. H SCHIEFFELIN & CO'S.,

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

105-15556

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

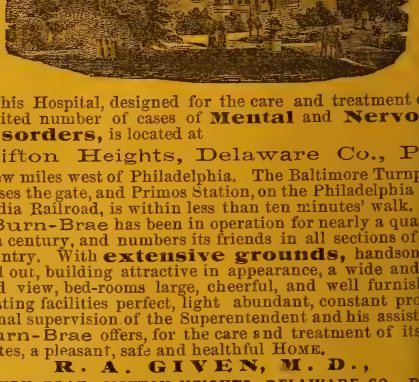
An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease-producing matter.

INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,
36 Platt St., New York.

BURN-BRAE.



This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful HOME.

LECTURES ON INSANITY.

DELIVERED AT THE UNIVERSITY OF PENNSYLVANIA.

BY CHARLES K. MILLS, M. D.,

Lecturer on Mental Diseases in the University of Pennsylvania; Consulting Physician to the Insane Department of the Philadelphia Hospital; Neurologist to the Philadelphia Hospital; and Professor of Diseases of the Mind and Nervous System in the Philadelphia Polyclinic.

Reported by William H. Morrison, M. D.

Lecture XI.

DELUSIONAL CLAIMANTS—WILLS OF THE INSANE AND TESTAMENTARY CAPACITY—ECCENTRICITIES SHOWN IN WILLS—LUCID INTERVALS—SENILE DEMENTIA.

Gentlemen: It is of importance that physicians, called in to patients who are likely to die soon, should make an examination of their mental as well as of their physical condition. With reference to wills, it is of the utmost importance that physicians who are frequently called upon as witnesses, or who are present at the time or just before and after a will is witnessed, shall in a most careful manner assure themselves of the mental condition of the patient. This is a wise thing to do in any case, and especially if the individual is a man of property.

An interesting phase of the insanity question with reference to wills, is that which pertains to delusional claimants. A certain type of the delusional monomaniac is an individual who believes that he has been wrongfully deprived of an inheritance. He is the man or woman in search of an inheritance. A number of such cases are to be found in every city. I know of several in Philadelphia. This is sometimes the only delusion in the particular case. A case was sent to the Norristown hospital by two physicians of this city. He remained there for a long time, and I was called upon, when consulting physician to the institution, to examine him in order to determine whether or not he should be discharged. He was also examined by Dr. T. G. Morton, of the Committee of Lunacy, and by the superintendent of the asylum. It was with the utmost difficulty that any legal evidence of insanity could be obtained. He talked as well as any one on ordinary matters, and he was upon his guard in reference to the few matters on which he was alleged to be insane. This man believed that some of his relatives had leagued together to deprive him of an inheritance. Evidence was brought to show that this idea was without foundation. In the case also were certain other interesting features which illustrate the curious way in which an insane mind will work. The delusion was in regard to this inheritance, and he wanted to get the advantage of those who he thought were depriving him of it. One thing which brought him into court and sent him to prison—for he was removed from a prison to the asylum—was to write most scurrilous and obscene letters to his own sisters, and to abuse them in other ways publicly. His idea was not to injure them directly by these letters and this public abuse, but it was to bring the matter of this inheritance of which he had been cheated to public notice, and thus make a great public scandal, and obtain what he deemed his just deserts.

The case came into court, through the Lunacy Committee, the superintendent and the assistant physician at the hospital, the two physicians that signed the certificate, Dr. Morton, myself, and others testified in the case, and the man was discharged by the judge, and I suppose is now at liberty. None of us were anxious to keep the man in the asylum. I simply testified that I believed him to be insane, and explained in detail the peculiar form of insanity; and stated that in all probability he might remain for months or years without giving trouble. The judge concluded that it was not proper to hold him any longer, and decided to give him a chance to enjoy his liberty as long as he behaved himself.

The office of the Register of Wills in this city is besieged sometimes by claimants of all sorts and kinds. In a former lecture, I spoke of the well-known case of Captain McCracken, a noted Delaware pilot, who believed that he was the heir to the estates of Jonathan Dickinson. Here is a Philadelphia newspaper account of a few of these delusional claimants. An old man with a fiery eye and a big red wig, marches up to the deputy's desk and requests that the $5,000,000 left to him by a prominent man recently dead be turned over to him at once. The officers learn that it is not always wise to deny these cases at once, but better to practice a little diplomacy. The clerk looks over a book and tells the party that the estate is not yet settled, and that he should come again, and bring his counsel with him. Not long ago a determined-looking young man came into the office with a bridle on one arm and a rope on the other, demanding a mule and a cow which had been left to him by his uncle. Another came in with a club over his shoulder. stating that he was the representative of her Majesty the Queen of all Britain and Ireland, the Emperor William of Germany, and King Humbert of Italy, and demanded that an inheritance be given him. These are simply illustrations of the delusional character of many of the claimants for bequests. From these absurd and ridiculous cases to the class of cases represented by the man before referred to who believed that he had been deprived of an inheritance, there are illustrations of all grades and degrees of analagous delusions.

I will conclude the lecture with a few words about the question of wills of the insane and the testamentary capacity of the insane. Not every man who is a lunatic (even under the law) is deprived of the right to make a will. A lunatic who has been certified to be insane, who has been declared by special legal process to be insane, and who has been an inmate of a lunatic asylum, has made a will disposing of his property, and this will has been upheld in court. That will show you at once that the mere fact of alleged lunacy or the existence of real lunacy will not in every instance enable a contest against a will to be successfully sustained.

Relatives are often unjustly deprived of their rights as a result of the peculiar mental condition of the individual at the time of making a will; and, on the other hand, those competent to dispose of their property, are unjustly alleged to have been insane.

The law is about this, that a person is regarded by the law as of a "sane and disposing mind if he knows the nature of the act he is performing and is fully aware of its consequences." These words are quoted from the law as found in text-books. This constitutes the phraseological rock upon which these questions are argued, but even this is capable of much discussion. A man may be aware of the nature of the act he is performing, and be aware of its consequences, yet he may be insane and do a very unjust act; but it is difficult to get a general principle to cover these important cases. It is like the old question of the plea of insanity in criminal cases, many arguing that we should make the knowledge of right and wrong on the part of the alleged lunatic the point about which the question of his responsibility should hinge. One thing must be borne in mind, that bodily disease, no matter what it may be, will not, under the law, incapacitate a man from making a will, unless it can be proved that the bodily disease has so affected his mind as to render him incapable of judging, or, in other words, has made him not of a disposing mind. Various special phases of this question are of great interest. The question of delusions in insanity with reference to wills, is one of these. It has been affirmed by courts that the mere fact of the existence of a delusion, or the fact that the person was a delusional monomaniac, would not invalidate a will. It practically comes to this: that in order to gain a case in a contest of this kind it must be proved not only that the person was a delusional monomaniac, but that the delusion was of such a character as to interfere with his just judgment in making a will. In other words, a man may have hallucinations of hearing, or sight, or persecutory delusions of a marked character, and yet he may be

able to conduct his business in a proper manner. Evidence could be brought in such a case to show that the man had been a delusional lunatic with hallucinations of hearing and sight for, perhaps, twenty years; and testimony equally strong might be given to show that during those twenty years he had not made a bad business contract. In such a case the will would probably hold.

In a day or two a case about which I have been professionally consulted, is to be tried in a neighboring county. The man is a delusional lunatic. This is admitted on both sides, and it is even admitted that he has committed a criminal assault, although not of a serious nature, under the influence of his delusion. Some time ago he was in an asylum, and the question came up in reference to the propriety of discharging him. The physician in charge of the institution and myself gave a guarded certificate stating that at that time the man was, to all appearances in a condition in which he might be given his liberty without detriment to society. Since then the man has developed more marked symptoms of insanity. An inquisition has been held, and he has been declared to be insane. The guardians are in doubt as to what they should do—whether they should defend his liberty, or whether they should submit to the finding of the inquisition and allow him to be put in an asylum, or under interdiction. The point in connection with wills is that this man with marked delusions, who has committed a criminal assault, has been shown to have business capacity, and while it might be doubtful how the courts should decide in case a question as to the validity of his will were brought up they would be as likely to sustain it as not.

Mere eccentricities and peculiarities in wills do not invalidate them. Thus recently a maiden lady, fond of cats, left a large portion of her fortune for the establishment of an institution for the care and comfort of cats, and I do not know that the validity of of this will has been questioned. A well-known gentleman holding certain peculiar views with reference to spiritualistic phenomena, left a sum of money to this University for the investigation of this subject. It might be held that owing to these peculiar views the man was not in a mental condition to make a will, but the courts would probably not sustain such a contest. Another case is that of a man who believed in the old doctrine of the transmigration of souls. He left a will, which held certain parts of which were supposed to be connected with this peculiar idea. Simple eccentricities or peculiar religious or other views are not sufficient to invalidate the testamentary capacity. Still, in not a few of such cases injustice has been done to somebody. An institution may get the money which should go to a deserving family.

One way in which the will of a lunatic is sometimes considered valid is on the old doctrine of lucid intervals. I was once asked in a lunacy trial by a dignified juryman, "Doctor, what is the difference between lunacy and insanity?" Practically, we do not recognize any distinction between the terms lunacy and insanity nowadays, but there is an old distinction. A lunatic in the old legal sense of the term was one who was insane but had lucid intervals supposed to depend upon the changes of the moon. This question of lucid intervals is one which is often brought up in will cases, it being claimed that although the individual was insane yet he had a lucid interval. A man in this city had an attack of apoplexy in the morning. He was seen every three or four hours by different medical men during the twenty-four hours before he died. It was claimed that during this time he had made a will. As far as the medical witnesses had seen he had been comatose much of this time. It was said that he roused up and made a will, but the will was not signed. It was said that he did not sign the will because of the paralyzed condition of the hand. This, however, is an extreme case. In many cases, as in circular insanity, where you have melancholia, then a lucid or sub-lucid interval, and then mania, etc., a will made between the attacks would probably hold in law. This old question of lucid intervals is an interesting one for discussion, and it is one on which contests are often based or resisted.

Senile dementia is another condition on which a contest of a will is often based. Some most interesting cases are of this kind. One recent case is that of a man in West Virginia, in which a number of those connected with the University have given testimony. This man conveyed his property to certain of his relatives before his death, and thus deprived some of his children of their inheritance. It is shown by a hypothetical question, which has been answered by physicians, that he was not in a state of mind to decide justly, because of senile dementia. Senile dementia is something more than the normal deterioriation of the aged. It is a peculiar disease with special symptoms.

COMMUNICATIONS.

PERIODICAL HYPERÆSTHETIC RHINITIS.*

BY JOS. BLOOM, PH. G., M. D.,
Of Baltimore, Md.

Already aware of the innumerable papers and pamphlets written and circulated, bearing upon this subject, I undertake from personal experience to make some practical remarks upon the same, feeling myself, to my sorrow, peculiarly well fitted to deal with the subject of my paper in a comprehensive and practical manner to which I invite your attention.

Having been a victim of this unwelcome annual visitor for the past twelve years, and having three friends similarly affected, I manifested deep interest in this disease long before I adopted the profession in which I am now engaged.

Previous to that time I dealt with it in a practical manner; now I deal with it in a somewhat theoretical manner, but the ultimate results from either treatment have not been as pleasing as could be desired. I can give no better or more comprehensive definition than that of Dr. Geddings, of N. H., in his article upon hay asthma, contributed to the recent excellent work of Dr. Pepper, which reads as follows: "Hay asthma is a form of catarrh appearing in the spring, early summer, or autumn, attacking persons predisposed every year at the same time, the patient being at other times free from the disease; characterized by symptoms resembling those of influenza; the chief of which are sneezing, redness, swelling, and increased secretion of the conjunctivæ, and the mucous membrane of the entire respiratory apparatus from the nose down to the minutest bronchi, frequently culminating in more or less severe attacks of asthma."

The interest recently manifested by the profession in the disease, is, no doubt, due to the increasing number of victims annually appealing to the practitioner for relief or possible cure. Not many years ago the practitioner diagnosed and treated the disease as a common cold or coryza, and I regret to say, with almost as much success as hay fever up to quite a recent date was treated. I remember that when in 1880 I confronted my medical adviser, one, too, of high standing, and stated I would like to be cured of hay fever, he replied: "My dear boy, if I could cure hay fever I would be a millionaire in a comparatively short time." Upon this reply, I, like all ambitious youths, eager to make lots of money in the shortest period of time, set to work experimenting with drugs and chemicals, without knowing the pathology of the disease; but, like my learned medical adviser, I found that the cure of hay fever would never reap me a fortune. From statistics which I have borrowed from the work of Merrill Wyman, the then prevalent idea that it was a disease of the cultured and educated members of society, seems somewhat plausible, from the fact that their temperament is more nervous than that of the multitudes engaged in manual labor.

Previous to 1860, the fact that the disease was unknown in Germany, where it is now known as "Hen Schnupfen," is substantiated by the honest confession of Phoebus, when confronted by a colleague suffering with the disease, that he was not acquainted with the disease, neither was its name familiar to him.

Of late hay fever has become as familiar and popular among the fashionable and intelligent classes as malaria and Bright's disease among the laboring classes. I will not enter into detail as to its etiology, nor touch upon the pathology at all, but to those interested I could commend no better work than the recently published one of Dr. Charles Sajous, of Philadelphia, or Merrill Wyman's, a sufferer like myself.

As to the cause of this disease, I am, and always have been at a loss, and from the literature I have read upon the subject, my conclusion is that all authors are at a loss as to the definite cause of this torturing malady. One will favor the "Pollen theory," and among the advocates of this theory are such learned authorities as Morrell Mackenzie, Moore, and Blackley; others are advocates of the "Thermic theory;" others advance the neurotic theory, and this I deem a true one, to the extent that a neurosis predisposes to the disease. This theory was advocated by Dr. John N. Mackenzie, of this city, and published in the year 1884 in the *N. Y. Medical Record.* Another advocates the individual peculiarity of the sufferer.

In its heredity I have no faith, unless the attack is accompanied or complicated by asthmatic symptoms, and I am strengthened in this opinion from the fact of having ten cases under my observation, in only three of which cases could the disease be traced back to the ancestors, and all three of the cases gave evidence of asthma.

Being exposed to the same causes of this disease as multitudes of others are, it most

*Read before the Clinical Society of Maryland.

assuredly must be some peculiarity in the person so affected, but up to the present such peculiarity has not been discovered.

I remember some years ago encountering in my flights to the mountain tops a negro afflicted with hay fever, a curiosity from the fact of not hearing or reading of another case among the African race. The disease is more common among males than females, and affects primarily those between the ages of fifteen years and forty years. From Wyman's statistics I note the fact that among ten professions the physician and medical teacher takes the precedence of all others in the percentage of victims of hay fever.

That the pollen is a cause, I almost hesitate to differ with such high and learned authorities as Blackley and Morrell Mackenzie, but that it is the excitant of an aggravated attack I submit, as a case now in my recollection, some years ago under my observation will illustrate: A lady whose husband is engaged in the grain business, and has a store-house well stocked with hay, straw, and oats, has her symptoms aggravated by his presence, or the removal of his clothing in her bedroom before retiring.

A peculiarity of the disease is the regularity of its invasion and recurrence. In the aforesaid case and my own the attacks recur annually on the 19th of August.

With those who hold that heat is the cause, I also disagree; but like the pollen it most undoubtedly aggravates the attack. The rays of the sun, or of artificial light falling into the room or upon the face of the victim will aggravate the attack. The electric light is innocent as compared to candle or gas light. My experience, like many others, has been such that a cloudy or rainy day is far more welcome to the sufferer than the sun in all his brilliancy, the symptoms being less in severity on such days. Having spent five years in the pharmaceutical laboratories of Messrs. Sharp and Dohme, of this city, where I manipulated and compounded many drugs and chemicals, my attacks were so severe at times that I was compelled to withdraw from the establishment for an hour or two. I noticed this especially in handling ipecac, quassia, senega, guaiac, or preparing the green or red iodide of mercury, a fact which would somewhat substantiate the pollen theory.

The first intimation that my foe is confronting me is a paroxysm of sneezing, malaise, and languor, soon followed by the army of symptoms, such as a tickling sensation in the fauces, nostrils, a roaring sensation in the ears. In the region of the frontal sinuses there is a sense of fulness shortly after these initiatory symptoms; the secretions from the eyes and nose become excessive and slightly acrid, constantly trickling down the face, causing excoriations of the adjacent parts.

The victim whilst suffering will seek solitude, avoiding his friends, and if possible his family. I have at times been melancholic, refusing to dine at the family table, and secondly from loss of appetite, which leaves me in a relaxed and depressed state after the siege has been fought.

As to locations exempt from the disease, my knowledge from experience is very limited, having only visited the mountains of our own and adjacent states.

I visited Deer Park and Oakland situated in the extreme west of this state, in Garrett county, at an elevation of 2,500 feet, and a temperature of 50° F., but my attacks were quite as severe, perhaps more so, when I reached the resorts, necessitating my return home before the week had ended. I also visited the Blue Mountain House, situated half a mile from the popular summer excursion resort, Pen-Mar, with a similar effect. The next place to which I took flight was at the request of my former kind and sympathizing preceptor, Mr. A. P. Sharp, to his country seat at Rock Hall, Kent county, situated about ten miles from Tolchester Beach, and about twenty-five miles from Chestertown. At this place I enjoyed comparative ease, as my symptoms were not so severe, which I attribute to the moisture emanating from the soil so adjacent to Rock Hall Creek, a tributary to the Chesapeake Bay. Since my last visit to this place, Mr. Sharp has made the observation that the atmosphere from Tolchester Beach on the bay shore, to the north of Chester river, is well charged with ozone. He also informs me that the physicians of Kent county are not acquainted with hay fever, and have encountered very few cases of neurotic asthma or phthisis.

Last year I took a trip to Europe, and on my return sailed from Bremen on 13th of August for America; although, as I have previously stated, my attacks regularly began on the 19th, on this occasion I experienced not the slightest symptom of hay fever until the 27th of August, when Sandy Hook was in sight, and then the disease attacked me in all its severity. This was sufficiently conclusive that the ocean did and does effect complete exemption, and I would advise such a voyage to those suffering, and finding such a voyage convenient.

As the greater number of my hearers are like myself engaged in the general practice of medicine, and do not possess the galvano-cautery, or other surgical appliances, neither have we acquired the skill and dexterity in manipulation of the rhinoscope and cautery, etc., as the specialist in the use of the same, I will therefore limit my remarks to the medical and hygienic treatment of the disease, which will undoubtedly confront us during the approaching months of June, July, and August.

For convenience, I will classify the treatment into local and general. The following receipts I have compounded and used whilst engaged in pharmacy:

℞. I. Quin. sulphas, ʒj.
Morphiæ sulphas, gr. j.
M. Use as a snuff.

I have also used this in solution.

℞. II. Bismuth. subnitras, ʒij.
Pulv. acacia, ʒj.
Morph. sulphas, grs. iv.
Sig.—Use as a snuff.

This was more satisfactory than ℞. I.

℞. Iodine resublimated, ʒj.
In a bottle filled with absorbent cotton and the vapor inhaled.

The good effect was only momentary.

During the remaining four weeks of my attack in 1885, I used a four per cent. cocaine nasal suppository, and a four per cent. oleate of cocaine dropped into the nasal cavity with a pipette, whilst in the recumbent position. The cocaine constringing the turgescent blood vessels, and shriveling the mucous membrane, thereby obtruding the sensibility of the hyperæsthetic nerve fibrilla situated in that organ. As a collyrium I have used the following:

℞. Boric acid, ʒj.
Aquæ rosæ, ℥j.
℞. Sodii biborat., ʒj.
Spts. vin. gallici, ℥ss.
Aqua camphor, ʒj.
Aqua puræ, ℥j.
A few drops into each eye t. d.

An infusion of green tea applied externally with a piece of lint had a soothing influence, no doubt due to the effect similar in its analogue, erythroxyllon coca.

Before retiring apply oleate of zinc ointment to the margins of the eyelids to prevent their adhesion in the morning, and if such adhesion should occur I use a lukewarm solution of bicarbonate of soda to the eyes.

As to the naso-pharyngeal and ophthalmic symptoms, internal medication has proved unavailing, but in cases accompanied or complicated by asthmatic symptoms, internal medication is highly essential, and for this purpose I can commend the following:

Morphia or codeia heads the list, but its administration should not be left to the patient's indiscriminate use. Bromide of potash or soda, valerianate of zinc or ammonia, Fowler's solution, fluid extract coca, or fluid extract grindelia robusta.

℞. Stramonium leaves, ʒj.
Belladonna leaves, ʒj.
Lobelia leaves, ʒj.
Anise seed, ʒj.
Tobacco leaves, ʒ ss.
These to be mixed and powdered, then saturated with ʒij of potass. nitras. in solution, then dried, and a teaspoonful ignited, and inhale the smoke before retiring.

As an alterative I have used:

℞. Potass. iodid., ʒij.
Tr. rhei, ʒ ss.
Tr. cinchona comp., ʒiiss.
M. Sig.—ʒj t. d.

This was also the tonic used by me.

In regard to hygienic treatment I have little to say. It is customary with me to take a cold bath every morning during the season, using the friction brush and Turkish towel quite vigorously; an unpleasant ordeal I confess, but an invigorating one, giving me an appetite for a light but nutritious breakfast, consisting of milk, soft-boiled eggs, and Vienna rolls or Graham bread.

My suppers are extremely light, owing to the insomnia and restlessness produced by an overburdened stomach.

During the entire season I use the London smoke glasses, which protect my eyes from the rays of the sun, also particles of dust floating in the atmosphere.

AS TO OUR LENGTH OF LIFE.

BY THOS. S. SOZINSKEY, M. D., PH. D.,
Of Philadelphia.

One meets frequently in the course of his general reading, and even in scientific publications, declarations to the effect that of late the length of human life, as well as the vital stamina of the race, has markedly increased. Some assert that the average age has been run up ten, fifteen, even twenty years, but a doctor of hygiene puts the case moderately thus: "The average duration of human life has increased, and all the evidence, I think, is in favor of the view that we are a better stock or race than we were a few years ago." "A few years" are sufficient to work material changes in the "stock or race!" Let the disciples of Darwin take notice.

The asserted increase in the length of life and vital force is attributed to more hygienic living, due in great part to the growth and diffusion of sanitary knowledge, which is said, of course, by the enthusiastic doctor of hygiene, to be a span-new science. Our forefathers were an ill-conditioned and ignorant set—they did not know anything about right-living. Shades of Hippocrates and other great lights of the past, take no offence at modern presumption!

Macauley spoke with great force, as was his wont, of the improved condition of the English people in his day. "The term of human life," said he, "has been lengthened over the whole kingdom, and especially in the towns;" but it is nearly forty years since the historian wrote, and, of course, the hygiene of forty years ago, according to the modern doctor, being of little account in comparison with what it is to-day, there must have been considerable addition since to "the term of human life;" for be it known that an increase of "the term of human life" goes *pari passu* with the modern "strides" in sanitary science. The day dawns, to be sure, in which men will live as long as the antediluvians!

Such statements are apt to be very agreeable to *amour propre*, but are they really true? Is the vital condition of the race improving?

The volume of the United States Census Reports of 1880, which has been issued recently, furnishes an interesting mass of plain, unvarnished facts bearing on the subject in question. During the census year it appears that of a hundred deaths reported forty were of persons under five years of age, fifty-two were of persons under twenty, and only twenty-two were of persons over fifty. Only about ten per cent. survive their three score years and ten. Twenty-four per cent., or nearly a quarter of the deaths are of persons between twenty and fifty years. Here is the table in detail:

Age.	*Deaths in* 100.
Under 1	23.24.
1 to 5	16.90.
5 to 10	5.71.
10 to 15	3.04.
15 to 20	3.89.
20 to 30	9.61.
30 to 40	7.60.
40 to 50	6.49.
50 to 60	6.22.
60 to 70	6.88.
70 to 80	6.38.
80 to 90	3.28.
90 to 95	.43.
95 to 100	.26.
Unknown	.42.

These astounding figures represent the mortality according to age, as already intimated, for the entire United States. For the thirty-one cities in which the deaths were registered during the census year the showing is far worse. "Under five years of age the proportion of deaths (reported) in the country at large was forty-three and seven-tenths per thousand of living population, while in the registration cities it was eighty-eight and four-tenths per thousand. In other words, the mortality of children under five years of age * * * was about twice as great in the cities as in the average of the whole country." So it is said in the Census Report. Of course, if a far greater proportion of the deaths in the whole country of persons under five years than of those older were not reported, which was certainly the case, the percentages given in the table of deaths of those dying at different ages of over five years, are much greater than they really ought to appear; for *il va sans dire* that the greater the number of deaths of very young people the lower is the average age at death. Even as the table stands, the average age is not far up in the twenties.

In France forty-eight per cent. of the deaths are of persons over fifty years of age; and what is more remarkable, twenty-five per cent. are of persons over seventy-years of age. The French present the best showing, except, perhaps, the Irish, of any nation as regards long life. Only about twenty-six per cent. of their deaths are of children under five years. About six per cent. only are of persons from five to twenty years.

For the purpose of comparison, the following table of the percentages of mortality at different ages in England and Wales in 1880 may be given:

Age.	*Deaths in* 100.
Under 1	25.48
1 to 5	16.98
5 to 10	3.66
10 to 15	1.73
15 to 20	2.23
20 to 25	2.61
25 to 35	5.51
35 to 45	6.36
45 to 55	6.88
55 to 65	8.75
65 to 75	10.06
75 to 85	7.66
85 and over	2.09

According to this table the deaths of persons from five to twenty years of age were less than eight per cent. of the whole; while in the United States they were over twelve. The deaths of persons from twenty to fifty-

five years of age were twenty-one per cent. of the whole; while in the United States the deaths of persons from twenty to fifty were more—twenty-four per cent. The deaths of persons over seventy-five years of age were about equal to the deaths of persons over seventy in the United States.

As serving to show how much other things than the advancement of practical hygiene have to do with the length of human life, the following table of the percentages of deaths at different ages in Ireland in 1880, is highly interesting:

Age.	*Deaths in* 100.
Under 1	13.98
1 to 5	11.60
5 to 10	4.00
10 to 15	2.53
15 to 20	3.41
20 to 25	3.85
25 to 35	5.62
35 to 45	5.78
45 to 55	6.54
55 to 65	10.77
65 to 75	14.05
75 to 85	13.30
85 to 95	3.72
95 and over	.80
Unknown	.05

Let the modern doctor of hygiene look critically at these figures. No nation of Europe is supposed to be more oblivious of sanitary science than the Irish, and yet a far greater percentage of the people of Ireland than of any other people, except the French, live to and beyond the age of seventy years. Nearly five in a hundred of the deaths are of persons over eighty-five years of age! Only about thirty-five per cent. of the deaths are of persons under twenty years of age. About forty-two per cent. of the deaths are of persons over fifty-five years. One-half almost of the deaths are of persons over forty-five years. In England and Wales, only thirty-three per cent. of the deaths are of persons over forty-five years, while in the United States only thirty per cent. are of persons over forty years of age.

Let the boastful doctor of hygiene say what he will, the vital condition of the people of neither England nor the United States is satisfactory; it is lamentably unsatisfactory. I know of no sound evidence pointing the other way. Appealing to the experience of life insurance companies does not meet the case at all, for the simple reason that the very young, the frail and the diseased, are very carefully excluded from regular insurance. Then, if the physical condition of the people of Ireland, a people poor and comparatively ignorant of sanitary science, is immensely superior to that of either, there must be influences at play in both England and the United States which much more than counterbalance all the beneficial effects of the sanitary science in practice in either country. Climate has something to do in the case, but the mode of living of the people far more. There is only too much reason for the belief that the very artificial mode of existence general in civilized countries is harmful. In other words, the less natural one's mode of living is, the more likely is his vital powers to become impaired. The multiplied appliances and complex ways of highly civilized life do not make for health and long life. The comparatively uncivilized do not suffer much from disease, or at least non-contagious disease, and their offspring are not doomed to die in great part in their infancy. The simple habits of those who live close to nature are most favorable to real human welfare. To live close to nature, which in general means in accord with nature—that is, the cardinal axiom which the doctor of hygiene would do well to specially inculcate. To this I may add, by way of conclusion, that Mephistopheles, who unlike the modern doctor of hygiene, was wont to say "*allwissend bin ich nicht*," gave Faust passing wise advice as to how to preserve his youthful health and vigor:

"Betake thyself to yonder field;
There hoe and dig as thy condition;
Restrain thyself, thy sense and will
Within a narrow sphere to flourish;
With unmixed food thy body nourish;
Live with the ox as ox, and think it not a theft
That thou manur'st the acre which thou reapest;
That, trust me, is the best mode left
Whereby for eighty years thy youth thou keepest."

THE ABSTRACTION OF BLOOD IN THREATENED APOPLEXY.

BY ENOS T. BLACKWELL, M. D.,
Of Cedarville, N. J.

The rebound that followed the excessive use of the lancet by our fathers, caused this remedial measure to fall into unmerited neglect. So fierce was the outcry against it that many physicians preferred to drop it from the list of curative means rather than to incur the opposition almost sure to be encountered, and the difficulties of enforcing its use. Hence, arose a timid and temporizing policy which interfered with its use at the proper time, and made its success dubious or not demonstratively successful. Here and there, it is true, might be found a prac-

titioner bold enough and sufficiently independent to employ any remedy that in his experience or in that of others had been attended with success. It has been the habit of the writer to bleed, in special cases, when requested to do so, to relieve ill feelings in the head of a person somewhat advanced in life, although the pulse was small and feeble, and the result was always satisfactory.

The following case, illustrating successful treatment in cerebral hyperæmia, threatening apoplexy, is deemed of sufficient importance to place before the profession.

On December 4, 1881, I saw Mrs. Phœbe H., aged 74 years, a farmer's wife, living in Warren county, this State, who gave the following history: She had always had good health till within a few years, when her mind and body had been taxed to its utmost in caring for a son whose health, mental and physical, had been wrecked by excessive study. She commenced to be dizzy in the summer of 1879, when she came near falling from this cause. She was also very sick at the stomach. In the spring of 1880, she fell while going up-stairs. She fell again the succeeding summer; her changed relation to objects about her leading her to believe that the furniture was toppling. She had many dizzy spells when she did not fall. In July, the year following, she would have fallen but for timely support. The dizziness was generally followed by sickness of stomach and excruciating pains in the loins for a short time. The attacks occurred frequently, and she would have all she could do to keep from falling. A month previous to my visit, she had pain over the right eyebrow, coming and going, and passing down the right side of the nose. She also had aching in the right eyeball. There was double vision in this eye, and objects appeared misplaced. She put a bandage over the affected organ, and the upper eyelid became paralyzed. She could discern objects by raising the lid with the fingers; but sometimes they appeared as if viewed through a veil. Her mind was wearied. The double vision lasted for one day only. The symptoms were present, in varying degree, until the time of my visit, objects appearing strange and distorted, and she was in constant danger of falling. Deeming that there was undue blood pressure upon the brain and nerves of special sense, and that there was imminent danger of apoplexy, I abstracted a pint of blood from the right arm, and prescribed potass. iodide 5 grains three times a day. The treatment gave some immediate relief, and, on the following morning some muscular power was manifest in the affected eyelid. December 13 she was to take a half-teaspoonful of fluid extract of ergot three times a day, with pil. hydrarg. every third evening.

I know not that any other treatment was used. All the evil symptoms disappeared, and her health was perfectly restored. There was no relapse until the latter part of February, or the beginning of March last, a period of over four years. She then had an uncomfortable feeling in the head, perhaps it might be termed a pain, which was constant. She was unsteady in her movements, and was confined mostly to her chair. She was now over 78 years of age; and the tottering gait gave an appearance of feebleness. The pulse was medium as to fulness and force. The gentleman who attended her could perceive no benefit from remedies skilfully employed; but was unwilling to let blood on his own responsibility, in the conditions named. I saw her on Saturday, March 13, meeting her medical attendant on the day following. Scanning the conditions carefully, and bearing in mind the positive success of the former bleeding, I unhesitatingly gave my voice for this measure, and one pint of blood was accordingly abstracted. The arm, when bared, was dry, withered, and flabby; nevertheless, a vein was easily opened, and the blood flowed freely and copiously. There was no flagging in the stream, when the amount was reached that was deemed proper to be taken; nor was there any faintness perceptible. There was an immediate change for the better, and my professional friend was enthusiastic in praise of the success of the measure, as were also the friends of the patient. The amendment was steady and assured, the patient at this time being in her ordinary good health.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Thursday, May 6, 1886. The President, B. F. Baer, M. D., in the chair.

Asepsis not Antisepsis. A Plea for Principles, not Paraphernalia in Laparotomy.

By Howard A. Kelly, M. D.

Medicine, like other branches of science, has been most retarded in its growth by the accumulation of all sorts of useless details. Some of these incrustations still clog the advance of abdominal surgery and will be given up with a notable diminution in the

general percentage of mortality. I refer to the use of carbolic acid and mercuric solutions at the operating table and to the continued use of any elaborate abdominal dressing.

The use of antiseptics in the patient's belly is full of danger and inconsistencies for the following reasons:

Firstly. If used in strength sufficient to certainly prevent sepsis, the patient is very often killed along with the germs. I have myself seen death from carbolic acid poisoning. The *American Practitioner*, November, 1881, p. 260, quoted by Dr. Goodell: "The first four cases done in the theatre at the beginning of last session had hemorrhage from the kidneys, and two of them died. I never had anything like that before. It was purely carbolic acid poisoning, of that I have no doubt whatever." Thos. Keith speaks of several cases in his own practice, and references might be indefinitely multiplied. Regarding the use of the bichloride solution, it is sufficient to say that its use has been very much curtailed in all maternity hospitals even as a vaginal wash. The danger line is here a very broad one for the limit appears only to depend upon the most variable of all factors, the individual susceptibility.

Secondly. It is the great tendency of all operators, and in particular their assistants, to forget the principle involved, and pin their faith to the accidental means of establishing it. This can be seen abundantly illustrated in almost any hospital in the land, where a clean napkin worked in and around the joints and grooves of the instruments in use, or carried under the nails of the operator's fingers, will exhibit sad evidences of soil. Then, too, the actual conduct of the operator is often modified by the false sense of security begotten by the incomplete use of antisepsis. I saw this well illustrated by a surgeon of more than local repute. The case was a herniotomy in which a large femoral sac was opened. The spray was throwing out a dense cloud, instruments and sponges were immersed in a two per cent. solution of carbolic acid and elaborate dressings were ready. A coil of intestine protruded from the wound for several inches, and it lay, first on the old hospital blanket below and then, in the effort to reach the ring, was turned upon the nightgown above. The antisepsis was here made a farce by these and other glaring inconsistencies.

If germicides must be used at all, let it be before the operation and in strength sufficient to neutralize any sepsis about instruments, sponges, etc. Then let the operator go to work with clean instruments, clean sponges, and clean hands, and he will need no antiseptic, and the patient's belly will no longer be a battle-field where germs and solutions fight often with such direful results to the host. It is my belief that it will not be long before the day of solutions will be past; and that in the future the successful surgeon will go to his work with pure water or dry pans for his instruments and fluid enough to cleanse sponges. My own practice has been to use hydrant water boiled for an hour and allowed to stand; or, better still, distilled water, as used by Professor Schroeder, and independently suggested and used by my friend, Dr. Jos. Price. I do not believe that reservoir water, dirty as it often is, ever contains any of the specific matter productive of septicæmia; but the process of boiling and using only the supernatant liquid makes it perfectly harmless.

Another fallacy discarded by some of the greatest operators, but perpetuated by many, is the transference of the use of the elaborate Listerian dressings of general surgery to the abdominal wound. These dressings so manifold and multiform, are clearly intended to prevent sepsis from penetrating the now closed abdominal wound. This is an accident which fortunately never occurs in the intraperitoneal method. The rapid agglutination of peritoneal surfaces effectively closing the sac. A sterile dry powder will absorb the slight serous discharge at the edge of the wound and suture exits, and above this some absorbent cotton and a firm bandage is all that is required.

While the danger of infection of the peritoneum through the closed wound is minimal, that of an infection of the belly wall through stitch holes is very great, and this is best prevented by the dressing recommended by Keith of carbolic acid and glycerine, one to eight parts.

With the mind thus freed from the notion that these solutions and dressings are accomplishing anything—from two such dangerous fallacies—operators at large will then work with a living consciousness of the real conditions of success, and they will then be on the alert from the beginning of the operation to its close, keeping within the mental horizon an exact knowledge of everything coming into contact with the patient's belly.

The expression of my convictions and practice will be of value in so far as they are in accord with the following letters upon the subject by the two greatest abdominal surgeons in the world, Lawson Tait and Thomas

Keith. Lawson Tait, in a letter dated March 15, 1886, to the writer, says, "I still use tap water and nothing else; it is never boiled; my instruments are prepared by being washed in soap and water merely. I use no elaborate dressings for the wound, never using anything at all except absorbent cotton wool.

"Yours very truly,

"Lawson Tait."

From a communication from Thomas Keith, of Edinburgh, written March 16, 1886, I make the following extract: "The secret in abdominal surgery, the secret in all surgery, consists in carrying out the antiseptic principle. You may do this in a simple way, or you may do it in a complicated way. All instruments, needles, forceps, sponges, etc., everything about the wound must be disinfected. A weak carbolic solution applied to the wound can do no good—nor harm. You may safely use hot water. My instruments, after an operation, are scrubbed with a nail-brush, especially the forceps points. This is repeated before the next operation with a 5 per cent. solution of carbolic acid. The greatest risk is that we put in septic matter on our hands, instruments, and sponges. Sepsis may come from the wound, but it rarely ever penetrates inside. I use a simple dressing of gauze, eight or ten folds soaked in one to eight carbolic acid and glycerine, extending two or three inches or so beyond the line of incision on all sides. Over this some ordidary cotton wool, a flannel bandage, and nothing else. Use this and you will never use anything else; and don't look at it for a week or ten days. You ought, for the patient's comfort, to put on an antiseptic dressing of some kind. You will probably often have suppuration with stitches if you do not. "Yours sincerely,

"Thomas Keith."

Dr. Montgomery feels great interest in Dr. Kelly's remarks, reinforced as they are by the letters from Tait and Keith. The antiseptic method of treatment has done a great work for surgery, and the successive steps of Listerism and cleanliness have brought it up to the comparative certainty of result now attainable. We can now eliminate almost entirely the antiseptic agents, carbolic acid, mercuric chloride, thymol, etc., and can do as well by the most rigid attention to cleanliness in all details of hands, instruments, sponges, and the skin of the patient. Some years ago he felt gratified that, in a patient upon whom he operated before a class at the Philadelphia Hospital with Listerism and the carbolic spray, the temperature did not rise above 102°. Now in his private hospital, with rigid attention to cleanliness and thorough washing of the peritoneal cavity with hot water, the highest temperature will be below 100°. After operations involving the opening of the peritoneal cavity, if there has been any opportunity for the escape into it of blood, pus, or cyst contents, he washes it out thoroughly with hot water. After closing the wound, he covers it with sublimated gauze and absorbent cotton, and secures this with strips of plaster and a bandage. This dressing remains a week without need of disturbance. If gut suture or silk rendered aseptic by a coating of wax with carbolic or salicylic acid be used, there will be no trouble about suture abscesses. In a recent case, in which the abdominal walls were two inches thick from adipose deposits, these precautions were observed and there was not the slightest suture trouble. He does not now consider the spray of any value, because we cannot use carbolic acid solutions strong enough to certainly destroy germs without poisoning the patient, and the spray only washes the germs down into the wound.

Dr. Charles Hermon Thomas remarked that the experiments of Dr. Sternberg, of Johns Hopkins College, a careful and conscientious observer, developed the fact that some of the antiseptic solutions in common use, three per cent. carbolic acid for instance, actually stimulated the growth of bacteria. Perfect cleanliness is the essential point, the foundation of surgical success. He has seen Dr. Kelly operate without disinfectants, his instruments being placed in a dry pan, and his results prove the truth of the assertions he has made this evening.

Dr. M. Price has experienced great difficulty in his attempts to secure absolute cleanliness. He has seen half a dozen unclean hands introduced into a peritoneal cavity during operation, simply from curiosity; sponges picked up from the floor, napkins from a dusty window-sill, instruments from a soiled blanket, and each used on peritoneal or absorbent surfaces; sponges that have been filled with pus used again in the peritoneal cavity, and, in general, extreme thoughtlessness in the little details of cleanliness that compelled the full power of antiseptics to bring good results. He has had good results in pyo-salpinx, even when purulent cysts have burst in the abdominal cavity, but he allows only the operator's hands to enter that cavity and practices the most thorough washing out with clean water. He has been burned by simply holding a carbolized ligature in his mouth for a few minutes,

and feels sure that the retention of a number of such ligatures in the abdomen would be quite likely to give rise to trouble.

Dr. Chas. Meigs Wilson said cleanliness by whatever means obtained is the great element of success in abdominal surgery. As absolute cleanliness can best be obtained by the use of agents possessing germicitic and anti-putrifactive properties, in the preparation of the atmosphere, the operator's person, the instruments, sponges, and dressings, it seems to be the part of wisdom to employ such agents up to the time of and even during the operation. With a perfectly clean room and furniture, clean air, clean instruments, and clean hands, possibly no antiseptic agent would be needed. But unfortunately such conditions do not universally or generally exist, and to attain them we must resort to the use of some efficient antiseptic. Care should be taken to employ some agent which is efficient and at the same time nonpoisonous. In English and Continental hospitals where excessive antiseptic precautions are employed, the success attained compared with the previous mortality rate proves unquestionably the great value of such precautions. The united testimony of experienced American operators as to the value of antiseptic precautions should not be set aside. I believe that all instruments should be submitted to the purifying influence of dry or moist heat. That the towels, sponges, and dressings should be left for twenty-four hours in a boiling-hot solution of mercuric chloride 1 to 200 and that the silkworm gut or fine wire sutures and ligatures should be kept in a very weak solution of carbolized oil. To my mind the terms antiseptic and aseptic are synonymous. My own experience has taught me that the best and least dangerous antiseptic agents are those which possess rather an anti-putrifactive power, *i. e.*, those which prevent or retard putrifactive changes, rather than the more dangerous class of agents which possess decided germicitic powers.

Dr. Parish. Antiseptics are not intended to take the place of cleanliness. The greater the care bestowed on cleanliness in all details, the less will be the need for antiseptics. Boiled water, filtered, is a good washing material; patient's hands and instruments must be clean to insure good results. Absorbent lint wet at time of using with a 1 to 2000 mercuric chloride solution is a good external dressing. Dr. Parish agreed with most of Dr. Kelly's statements, but he believe in the value of antiseptic vaginal injections after labor in hospitals. The maternity wards of the Philadelphia Hospital showed a large number of deaths, ranging from three to ten per cent. for many years prior to 1885; but last year in two hundred and forty-seven cases of labor there were but two deaths. One of these was after Cesarian section in a patient who had been in labor nearly three days before she was brought in to the hospital. The other fatal case was in an idiot, and was largely from other causes than the labor which was not at fault. These good results are due to the use of mercuric chloride injections principally although we have now new wards and opportunity for frequent change of nurses when advisable. In a case of septicæmia following adherent placenta, the patient seemed almost moribund, but hot uterine injections of mercuric chloride, 1 to 4000, stimulated her and led to recovery. Water is boiled to destroy possible germs and filtered to get rid of various impurities not held in solution.

Dr. M. Price thought the heat of the injection used by Dr. Parish was the most important element in stimulating the patient, but the mercuric chloride would do no harm, and the fact that improvement commenced and continued from that time is the important point. The reaction against the use of antiseptics should not be allowed to go too far. They have done great good, and can not be discarded.

Dr. Longaker agrees with Dr. Parish, and regrets to hear any disparagement of antiseptics. No reputable maternity can be conducted without them. Dr. Lusk considers that the poor woman delivered in the hospital with the protection of antiseptics is safer than the rich woman in her home with every other safeguard but without them.

Dr. Soper, formerly of the Rotunda, Dublin, upon invitation from the president, remarked that this was a very mixed question. That neither cleanliness nor antiseptics could be dispensed with. He has seen cases do well under all conditions without antiseptic precautions, and if the solutions are dangerous we must be cautious in their use. He believes thoroughly in cleanliness, and would use antiseptics when he thought them needed. It does not do to run into extremes.

Dr. Kelly replied, in closing the discussion that he was both surprised and gratified that so many members of the Society had expressed their approval of this paper. In two or three instances, however, he had been grievously misunderstood. He believes it to be the great glory and the crowning triumph of *antisepsis* to have discovered *asepsis*. He had nothing whatever in common with

those surgeons who claim that antiseptics have done nothing. The peritoneum is a vast, exquisitely sensitive "culture" sac. In the old time chance decided whether the uncleansed hand of the surgeon carried in suitable germs to multiply in the medium, and the chances were greatly against the patient. Now the use of antiseptics accidentally involves rinsings and cleansings, which make the surgeon a clean man in spite of himself, and the patient generally escapes. In a more advanced position, and the one in which the surgeon is living up to a *principle*, the utmost precautions are taken by a preliminary use of antiseptics in sufficient strength, and he goes to his operation needing no germicides.

Let the battle-field be without the patient's belly, and the germicides will there be sure of a victory every time. Statistics from foreign maternities as quoted, instead of proving against, are one of the strongest arguments for this position, for there the use of the germ-destroying agent is wholly *without* the patient's body.

Dr. M. O'Hara reported a case of

Extra-uterine Pregnancy, with Rupture of the Fallopian Tube. Laparotomy on the Thirty-third Day. Recovery.

On September 25, 1885, Dr. O'Hara was called to see R. H., who had been in good health until seized, two hours previously, with severe rectal tenesmus, agonizing pains in the pelvis, pains from both flanks, and extending down the right leg and arm. From the tenesmus she thought she would have a stool, and rushed to the water-closet, but no relief following, rushed to her room, and fainted; she was carried to bed, rectal injections were given by those present, but no movement followed, and opiates were given her for the relief of the pain. When I saw her she was in collapse, almost pulseless, respiration shallow, extremities cold. The whole surface was bedewed with a cold death-sweat. She could not lie on her left side or back, but reclined doubled up on her right side, and would jump occasionally with exclamations of agony. The history hastily gathered gave the following data: R. H. was thirty years of age, mother of three healthy children, the youngest one year old; she was still nursing it. She had never been sick, and had menstruated regularly. One menstrual period had been missed about a week before the accident, and she considered herself pregnant.

The diagnosis was internal hemorrhage, due to rupture of the fallopian tube at the fifth week of pregnancy. Opiates and stimulants were used. The next day Dr. Parish was called in consultation, and concurred in the diagnosis. There was still some shock; pulsation 130, feeble and irregular; respiration feeble; temperature normal; great pallor, evidently due to the loss of blood; the abdomen was moderately distended, with occasional cramp-like pains; moderate tenderness, but no symptoms of peritonitis. The patient showed signs of reaction, and laparotomy, though discussed, was deferred. Five days after the rupture, the patient was able to bear a close examination. The abdomen was greatly distended; there was no tenderness on moderate pressure; resonance was general, except in right flank, where there was moderate dulness; there was no dulness in the left iliac and lumbar regions, except very far back near the kidney. There was an apparent bulging of the right flank. The vaginal surface was generally œdematous; the anterior wall of the vagina was thicker at the cervix and to the left. The cervix is moderately soft and patulous; no bulging of the posterior pouch. It was not deemed advisable to use the sound. The urine was almost black in color. Pulse 104, temperature 99°, respiration normal. Two days later a marked jaundice appeared, although occasional vomiting and purging of bile occurred. A few days later a swelling was noticed on both sides and in front of the cervix; and a bloody, painless discharge, containing decidua-like fragments, escaped from the uterus, and the dulness in the right iliac region disappeared. Urination became painful and difficult. The patient felt so much better that she desired to get up.

Three weeks after the first attack a terrible flooding occurred, it lasted for an hour, and slight hemorrhage continued afterwards. There was decidua in this discharge. At the same time the supra-pubic tenderness extended towards the right and slightly increased on the left side, extending upward as high as the umbilicus. Chills and a rise of temperature to 101°, vomiting, constant, sharp-cutting pains, and emaciation, with signs of softening along the crest of the ileum, and general appearances of blood poisoning occurred, and surgical interference was strongly urged as the only means of averting death. On the thirty-third day Dr. Parish operated, and he prepared the following report of the operation.

There were present Drs. O'Hara, R. P. Harris, DeF. Willard, and McElroy. I proposed to cut down directly on the tumor by an incision immediately above the outer

portion of Poupart's ligament, believing that the tumor consisted of blood coagula and pus, located external to the peritoneum, and that the anterior parietal peritoneum had been dissected up to such an extent that the mass could be incised and emptied without opening into the peritoneal cavity, and without incurring the possibility of objectionable fluids reaching the serous surface. I also believed that the peritoneal cavity was clean, and that there had been no general peritonitis.

The gentlemen present advocated a median incision for purposes of exploration, and in deference to their views, I first cut through the linea alba, just below the umbilicus, making an incision long enough to admit two fingers. The peritoneal cavity was found empty, and the peritoneum quite normal, though somewhat congested. The exploring finger showed that the mass was external to the peritoneum, and had extended upward from the left half of the pelvis to a level with the umbilicus. The broad ligament had become obliterated by separation of its layers. It was not thought advisable to explore with the finger with the view of determining the condition of uterus and ovaries and tubes. The peritoneal covering of the abdominal accumulation was evidently thin and tense, so that a careful exploration as to the condition of the uterine appendages would have endangered its rupture and the probable development of general peritonitis. It would have been an easy matter to have stitched the parietal wall of the tumor to the walls of the median incision, and to have then by incision emptied the mass of its contents. But such a procedure would have been attended with risk of leakage of the offensive fluid into the peritoneal cavity. To avoid this risk, I now made another incision along the line of the original election, *i. e.*, above the outer border of Poupart's ligament, and readily reached the mass cavity without wounding the peritoneum. This incision was made long enough to admit two fingers. About one quart of blood coagula, fluid blood, and pus escaped. The fibrinous masses were removed, and all attached portions were scraped off with the fingers. The curette was avoided, chiefly because of the thin upper wall. The cavity was washed out with antiseptic fluid.

The median incision was closed with sutures, a drainage tube was introduced into the mass cavity. An incision could not have been safely made through the vagina, as the intervening tissue was too thick and its vascularity too great. The incision made admitted of more thorough emptying of the cavity.

The patient suffered no shock from the operation. There was a slight sanguinolent discharge, containing small clots, from the drainage tube, amounting to about two ounces in twenty-four hours. Nourishment was taken fairly. The cavity left at the time of operation held f℥xxxij. In two days it had contracted to f℥j., but the discharge was purulent and offensive. A bloody discharge from the uterus had continued since the operation, but was free from odor and diminishing. The last sutures were removed five days after the operation, and two days later the drainage tube was replaced by a tent. Two weeks after the operation the uterine discharge had ceased, but free bleeding from the wound occurred; there had been no exertion, sneezing or coughing to cause this hemorrhage, which occurred about eight weeks after the last menstruation, but a week later a bloody discharge occurred from the uterus and wound. The temperature rose to 103°. There was no pain on pressure, but there was a suspicious hard spot in the left iliac region. Twenty-four days after the operation the patient was permitted to sit up, and while cheerfully singing, felt blood streaming down her legs from the wound; clots passed also from the uterus and rectum. She felt the rectal tenesmus and pains in right lower extremity similar to those felt at first seizure. Much blood was lost. A similar bleeding occurred three days later, and as life was endangered it was thought necessary to give ether and explore the cavity. It was found that the tissues had been dissected up by accumulated blood and pus, until the cavity extended down the side and front of the uterus, and communicated with the rectum at the upper end. The cavity was thoroughly scraped with a curette, and was then packed with alum sponges after disinfection with Platt's chlorides. The patient reacted well. When the wound was injected nothing came from the rectum, but an injection into the rectum came out of the wound, and there was a fecal odor about the wound. Next day the sponges were removed, and muslin tampons wet with phenol sodique were introduced. The packing was changed twice each day. Discharges of offensive fecal matters, and a small gallstone escaped from the wound.

On February 15, nearly four months after the operation, the patient is noted as doing uniformly well; the wound is closing; the exudation about the uterus and vagina is disappearing, and the odor and elimination of

gas while dressing the wound had disappeared.

May 1. Patient has gained greatly in flesh, and presents the appearance of perfect health. A very small short sinus alone remains. The communication with the bowel has closed entirely. Menstruation occurs normally, and there is no bleeding at any time from the wound.

Dr. Parish made a few remarks upon the history of this case, and the difficulties surrounding a diagnosis. The patient was thirty years of age, and perfectly healthy. She missed one menstrual period, and a week later, possibly in the fifth week of pregnancy, there were signs of internal hemorrhage with shock. Dr. O'Hara at this time made his diagnosis, doubtless correct, of tubal pregnancy with rupture of the cyst. The patient commenced after a few hours to rally. Dr. Parish was called in consultation the next day; he suggested an operation to remove the cause of the trouble, but did not urge it, as the symptoms had ameliorated. The patient continued to improve for several days. Afterwards a tumor appeared. The first hemorrhage being into the folds of the broad ligament and limited, did not show, but as repeated hemorrhages occurred the tumor increased, pus formed, the embryo softened, septicæmia without peritonitis was developed, and then the operation was performed and was then imperatively demanded. Three months after the original shock a sudden and nearly fatal hemorrhage occurred simultaneously from the wound, vagina, and rectum. Evidently there was a tubal communication between the uterus and the wound, and a large rectal fistula had formed. This fistula healed without any separate operation.

There was evidently at the beginning a pelvic hæmatocele without peritonitis, due to a ruptured fallopian tube. The early operation was proposed, but did not meet with approval. It was evident the hemorrhage was extra-peritoneal, as it would probably have been fatal if it had burst into the peritoneal cavity. He deprecates the expectant plan of treatment of cases of rupture of the cyst of tubal pregnancy, but in this instance the amelioration of the symptoms at the time when first seen by him led him to hesitate as to the necessity for immediate operation. The sequel showed that in this case an early laparotomy would have been of no service. The patient's recovery is complete.

Leyden on the Treatment of Obesity.

Professor Leyden, President of the Society of Medicine at Berlin, summarizes the experiences and opinions set forth in a discussion on the above subject, as follows (*Der Fortschritt*, No. 10, May 20, 1886, from *Deutsche Med. Wochensch*).

I fail in concluding, from the present debate, that one method of treatment may claim a signal superiority over the others; and my own experience in practice confirms me in this view. It seems to me that all the various methods possess nearly the same merit; every one of them, when judiciously persevered in, producing the wished-for result. We certainly may regard it as a material practical progress, to be enabled now-a-days to have at our command several efficacious methods of treating obesity, of which we may select that most suitable to the nature of the individual case, being at the same time agreeable to the predilection of the patient. As a general rule, we ought to be guided by the etiology of the case; *i. e.* we have to withhold that kind of aliment on which the patient has grown abnormally fat. Therefore the problem how to reduce the superfluous fat in a patient cannot be of great difficulty. The leading principles to achieve this—viz., limited ingestion of food and increased structural metamorphosis, assisted by muscular exercise, are very old, but our means of accomplishing it have enlarged. The treatment, above all, ought not to endanger the general health, and ought to lead to success without the least possible inconvenience to the patient. These two conditions form the main pivot of the present discussion. Without, however, some self-denial, the necessary abstinence cannot be carried out. All the various methods, notwithstanding their apparent diversity, agree in the reduction of food; and the modern limitation of liquids (Orth's method) is in fact nothing else. Some persons can more easily endure thirst, others hunger.

Nor can I perceive a material indication

of one method being more effectual than another. With due circumspection and perseverance, every one may finally succeed. But, at the same time, all these methods are fraught with some danger; anæmia, exhaustion, and especially debility of the action of the heart, not uncommonly ensuing after such anti-fat cures, when carried on too energetically and without discrimination. Such injurious consequences may even arise, when the treatment has been undergone with proper precaution and patience. There are many fat persons, whose proper condition of health requires a certain degree of stoutness: they will become ill and weak as soon as they lose fat. The physician, therefore, ought to consider the individual nature. Young persons, on the other hand, especially men who have grown stout from too liberal indulgence in beer or at dinner parties, will soon and without danger be reduced and brought into proper condition by due limitation of their self-indulgent habits.

The selection of the method ought to depend not only on etiological considerations, but on the individualizing judgment of the physician, and partly on the preferences of the patient. And in the latter, undoubtedly, fashion plays a very pre-eminent part. No experienced physician will disregard the influence of fashion on medicine and therapeutics; fashion constitutes, I aver, a remedial agent which the physician has, in some degree, to acknowledge. Patients have more confidence in remedies which are of the fashion of the day, and more willingly submit to deprivations enforced by a treatment if this happen to be in fashion, *i. e.*, if a number of well-known leaders of society and of their personal acquaintances have accepted it.

This influence of fashion we have met with in a remarkable manner in the different methods of treatment of obesity. Twenty years ago Banting's cure was in fashion, which, if used with certain rational restrictions, I still consider the best treatment. At that time persons of the better classes, who fancied or observed the slightest propensity to become stouter, adopted Banting's dietary. At present, for the same reason, they barely dare to partake of soups, and either limit to the utmost their drinks, or entirely abstain from liquids, and consider thirst a far less severe penance than any other kind of treatment.

Stout people resort with good effect to mineral waters and baths, losing there from ten to twenty pounds, thus preparing themselves for the dissipations of the coming season. They consider it a far smaller ordeal to submit for four to six weeks to the strictest abstinence in order to indulge during the remainder of the year in every luxury of the table, than to regulate their diet and to deny themselves any gastronomic enjoyment all the year through.

The rational treatment of obesity certainly falls within the province of the physician. Obesity, if not a pathological symptom, causes much discomfort and inconvenience, and may lead to various morbid conditions. Even if an individual be desirous of getting rid of superfluous fat, on account of his personal appearance, a physician ought not to withhold his advice. But, in meeting the wishes of the patient, it must be well borne in mind that there are very different constitutions. We know that some families are spare made, others very stout; it is the physiological condition of the former that all its members be lean, and of the other that they be fat. Not everybody, therefore, can become thin; and if people, who, in a certain condition of stoutness feel thoroughly well, attempt to lose fat, even only moderately, very serious symptoms might arise.

In concluding with a few words on the history of this subject, I may point out that the problem of the anti-fat cure is by no means one of the exigencies of modern times, but is coëval with medical science, or what in most remote antiquity passed for that. Hippocrates has laid down hygienic and dietetic rules for the prevention and the treatment of obesity, which are too well known to require further allusion. I shall confine myself to quotations from Galen and Celsus. The former gives the following advice:

"The best method of getting thinner consists in gradually withdrawing from the body that whereof there is superfluity, and in strengthening at the same time those parts which had been expanded. Bodily exercise will undoubtedly prove very advantageous, as we see stout horses getting lean by heavy work. Thus, likewise, those will never grow fat who are obliged continually to toil with hard labor. This, however, requires great precaution, it being certain that fat people frequently run dangerof death when attempting violent bodily exercise." And Galen says: "Regular alvine motions, energetic bodily exercise, a moderate life, a diet which, although satiating, yields but limited nourishment; which explain why Hippocrates advises stout people wishing to grow thin to dine on vegetables cooked with fat, in order that they may become satiated by a small quantity of food."

The Treatment of Chronic Heart Disease.

The observations of Dr. Schott, of Nauheim (*Berliner Klin. Wochensch.*, 1885, Nos. 33–36), since 1871, extend over 300 cases, and the clinical histories of a fair proportion of these are followed up. It will be remembered that Stokes was the first to advocate a life of active exercise in chronic heart disease. Indeed, Stokes went so far as to say that, for a man with well-compensated valvular lesion, the greatest misfortune that could happen to him was to have his cardiac trouble discovered by a medical man. This was because a number of restrictions were, as a rule, imposed upon his usual mode of life, all tending to a debilitating illness. The consequence was that the heart-muscle, like the other muscles of the body, lost strength, and dilatation of the heart supervened earlier than would otherwise have been the case. Stokes's doctrine of the positive value to the heart of a life of activity, has received more attention on the Continent than amongst his own countrymen. In Germany, especially, it has been developed into a complete system of treatment, on various lines. Oertel, as is well known, prefers hill-climbing to any other method, care being taken to ward off any threatening dyspnœa by repeated stoppages, and by making a few deep voluntary respirations before proceeding. This mode of exertion is selected partly also from a desire to unload the venous system, and the right side of the heart in particular, by diminishing the volume of the blood generally; and the excessive perspiration induced by mountain expeditions does this gradually and effectually, the supply of liquid being duly restricted by removal of the excess of water from the blood.

Dr. Schott makes great use of stimulating baths, together with the systematic exercise of the various muscles of the body at home by the aid of an assistant; but the bath is made apparently the chief element of the treatment. An artificial Nauheim bath (apart from carbonic acid) may be rudely imitated by adding to softish water 1 to 1½ per cent. of common salt, and as much per mille of chloride of calcium, the temperature being 93° F. Very weak patients have the water a little warmer, but not beyond 96° F.; and in all cases the bath should be a short one, a second chill being avoided. The baths are gradually made stronger, cooler, and the patient remains in longer, according as he improves. The full strength is from 2 to 3 per cent. of chloride of sodium, and from ½ to 1 per cent. of chloride of calcium, with carbonic acid. The last-named may be supplied artificially by adding equal parts by weight of bicarbonate of soda and hydrochloric acid, the full strength being 1 kilogramme of each in a bath of 250 litres. But much smaller quantities suffice at first.

The exercises consist of various movements of the limbs and trunk, each movement being opposed by an assistant, who gives way as the patient exerts his strength. The greatest care is taken that the patient breathes easily the whole time. The details may be found in Dr. Schott's original article (*Berlin Klin. Wochensch.*, Nos. 33–36, 1885,) reprinted as a pamphlet by Schumacher, of Berlin.

The therapeutic results have already been summarized in these columns. Suffice it to say, that diminution of the cardiac dullness during a course of baths can be actually demonstrated, and, as a rule, the improvement in the patient's condition is immediate and striking.

No alteration is made in the solid food, but Dr. Schott has for years restricted the fluid supply whenever high arterial pressure existed. Finally, mountain tours are recommended where there is obesity, but in moderation.

This system of baths and exercise is a rival to Oertel's mountaineering system, and possesses certain advantages, in that it can be adopted at home, and can be regulated to a nicety to suit the patient. But Dr. Schott's observations lack the scientific precision of Prof. Oertel's. It is earnestly to be hoped that a more active life may be ordered by medical men generally in the treatment of heart disease. It is to be feared that a merely passive existence is still widely recommended to any unfortunate patients with (mitral) valvular lesion and dyspnœa.

Night Palsy.

Dr. W. E. Steavenson thus writes in the *Practitioner* for June:

I have had several cases of this affection sent to me for treatment in the Electrical Department at St. Bartholomew's Hospital, and venture in this paper to give a review of the subject, and to record the opinion I have formed of the nature of the complaint. All my patients have been women, usually at or near the climacteric period of life. Some few had passed it by a year or two. I have seldom seen the affection in an old woman, but I remember to have seen one case over the age of sixty years. I have also met with it in women between the ages of thirty and forty years. The attacks have very

often followed a hard day's work, such as washing and scrubbing, or have been due to other causes producing nervous exhaustion. The patients have usually been awakened towards morning by tingling and pain in the arms. The limbs seem swollen, and there is a sensation of bursting and fulness. Real swelling is very slight, if present at all. Patients cannot raise the arms to the head. Sometimes with a little rubbing the arms recover somewhat, but after raising them for a short time, for such a purpose as dressing the hair, they again become useless, much in the same way as with a painter who is working at a point above his head, and has to rest his arms occasionally on account of the useless feeling which is so produced in them. This fact might be used as an argument in favor of Dr. Notley's theory that the affection is due to anæmia. Patients who suffer from this form of paresis often have a dread of impending paralysis, and look upon these morning attacks as premonitory symptoms. After a short time, with rubbing, the numbness and loss of power pass away. When tested by electricity the muscles of the limbs react normally to both the continuous and interrupted currents.

I have been led to consider this affection a functional derangement of the nerves, occurring for the most part in women at or about the climacteric period, and in my experience appearing more likely to occur in women of an hysterical temperament. I believe that the period of the menopause has a decided determining influence on the occurrence of these seizures. As Dr. Saundby says, "we are all familiar with the various forms which neurasthenia takes in climacteric women," and I believe that this "special form of numbness of the extremities" is one of them. At or about the time of the cessation of the menstrual function, women's nervous systems undergo a profound change. Often at this time nutritive changes are also apparent. A thin woman becomes corpulent; those with any tendency to the growth of hair on unusual parts again develop it, although the growth may have ceased or almost disappeared during the child-bearing period; the tendency to the return of hysterical symptoms is also most common. All the patients I have seen who have suffered from this affection have been women, and in this I agree with most other observers. It very possibly occurs as often in men as true hysteria does. The coffin-maker described by Weir Mitchell as being troubled with some form of this complaint, was a poor, weak, hysterical individual.

The suggestion that this affection may be due to gastric irritation is new to me. Dyspeptic symptoms were certainly not prominent in or complained of by my patients. All the cases I have had have recovered with rest, bromide of potassium, and galvanism.

A Rare Case of a Gun-shot Wound, with Recovery.

Dr. C. K. Gregg, of Ramos Arispe, Mexico, reports this case in *Daniel's Texas Medical Journal:* Philippe Delbosque, æt. 21, whilst imbibing too freely of a favorite Mexican liquor, "pulque," at a "pulqueria," on Sunday afternoon April 28th, attempted to draw his pistol, a 45 cal. S. & W. (secreted under his vest, and between his pants and shirt), and which was accidentally discharged.

He was removed to his home at once, and seen a few moments after the accident. I found that the bullet had entered the hypogastric region of the abdomen, to the right of and above the bladder, taking a downward and oblique course, and making its exit from the body at the apex of left testicle, producing a slight wound on the inner side of the left thigh, and lodging in his drawers. As he had passed his water shortly before my arrival, and which was free from blood (the bladder having been quite distended prior to accident), I came to the conclusion, therefore, that the bullet must have passed above and near the neck of the bladder, without injuring that important viscus, under the symphisis pubis, and following the spermatic cord made its exit as above stated. Hemorrhage was slight, but shock very great; however, as apparently the bladder had not been injured, I gave a favorable prognosis. Fearing subsequent peritoneal trouble, the bowels were ordered to remain at rest, and all purgative interference strictly prohibited. He was given a hypodermic of morphia, and cold applications applied to both wounds; liquid diet, and absolute rest enjoined, for fear of secondary hemorrhage.

For the first few days he did exceedingly well, with the exception of suffering some pain, which, however, was easily relieved by hypodermics of morphia. On the third day he had some fever, temperature reaching 101° Fahrenheit (highest point reached).

On the fifth day suppuration commenced from the lower wound, and on the same day pain in testicle and abdomen was excruciating. Scrotum, penis, and left iliac region of abdomen became ecchymosed and remained so until convalescence was well estab-

lished. Suppuration, especially from the testicular wound, was very profuse, lasting nearly two weeks.

No symptoms of peritonitis manifested themselves, which I attributed in a measure to the quietude of the bowels for the first eight days. He always passes his water freely except when under the influence of morphine. About the eighth day he was greatly annoyed by nausea and gastric irritation, which, however, was easily relieved by an effervescent mixture of pot. bicarb. and acid tartaric. When cold applications were no longer necessary, the remainder of the treatment consisted in applying iodoform and zinc ointment alternately over the wounds, which caused them to heal very quickly.

In less than one month my patient was able to ride on horseback and attend to his duties as "*gendarme*."

Case of Congenital Deformity of the Chest.

Before the Liverpool Medical Institution, Mr. Bernard Blower showed this case, which was one of congenital deformity of the chest, which the author considered to be of interest chiefly from the amount of deformity with comparatively little apparent disturbance of the functions of the contained viscera. The patient was a young man, æt. 21, with a good family history, employed in the London and North Western Goods Station, where he had charge of a hydraulic capstan, and although his work is rather laborious, and his hours long, he has been able to continue pretty steadily at it for the last five years. There is no history of any obstructive disease of the air passages during childhood to account for the deformity, and although he has always been delicate, he states that he has never been actually laid up by any illness, with the exception of an attack of bronchitis three years ago, and since then has been subject to a winter cough. When he presented himself as an out-patient at the Chest Hospital two months since, he complained of cough, and slight difficulty in breathing. The deformity consists in an approximation of the anterior and posterior chest walls in the middle line. The second piece of the sternum was bent at an angle about the centre, the apex pointing backwards, so that a large cup-shaped depression is found in the front of the chest, which when the patient is placed on his back holds about ʒx of water. There is a lateral and antero-posterior curvature of the spine forwards, so that when the fingers of one hand are placed in the depression before mentioned, and those of the other hand in the depression in the back, the tips are only separated by about three inches. If the space occupied by the spine and body of the vertebra, and the thickness of the sternum be subtracted from this distance, the cavity of the chest in this situation, viz., the anterior mediastina and posterior mediastina, must be almost entirely obliterated. The heart appears to be placed almost in a perpendicular position, and contained entirely in the left half of the thorax. The superficial veins upon the surface of the chest are slightly distended. The lungs appear to be healthy, with the exception of a few bronchial rales posteriorly, and some fine crepitations at the apex of the left lung anteriorly. I have no doubt that rickets was the original cause of the deformity, although the chest has assumed an unusual shape, and the only remaining diagnostic sign is some slight enlargements at the junction of the ribs with the cartilages.

Constipation and Epilepsy.

Dr. J. S. Jewell thus writes in the *Neurological Review* for June: The general profession has yet much to learn in respect to the bad influence upon health of habitual distention of the colon with fæcal matter. It has also much to learn as to other efficient means for emptying the bowel than the ordinary purgative, such as the pills and cathartic powders, extracts, salts, and natural mineral waters charged with the same. In many cases it is not only desirable, but entirely practicable, to cease the use of drugs to purge the bowels. Where the colon is much weakened in its muscular coat, and chronically dilated, it can not possibly be fully emptied by such means. I have known distention of this part of the intestine to be so great that from one to more than two gallons of matter have been removed in the course of two or three days devoted to the task of emptying the colon of rotting materials. I wish to repeat my conviction that no other point in respect to the hygiene of epileptics more worthily challenges the persistent attention of the physician than the one just referred to. In cases where there is reason to believe filling up of the bladder with urine, and unusual distention of the seminal vesicles, irritate the organs in question, and by consequence the copious nerve supply of the same, I am accustomed to direct at least that the bladder shall be emptied at an earlier period than that upon rising, so as to anticipate the fit. In bad cases of

epilepsy, in females, in which by consequence marriage is out of the question, I have been led to seriously consider the desirability of removing the ovaries, and of thus putting an end to the menstrual history. My opinion is that in bad cases of epilepsy, occurring in early and middle life, plainly connected with and dependent on menstrual disorders, the operation in question ought to be attempted, with the prospect of greatly ameliorating the attacks. Then, again, I am accustomed to direct my patients to avoid as far as practicable serious fatigue, whether physical or mental, and all undue emotional excitement at those periods when they are known by experience to be likely to have the attacks. For, in case of great fatigue, both the sensibility of the nervous system, as a whole, is sharpened, and its inhibitory power diminished. These, it need scarcely be said, are prime conditions, not to say causes, of attacks of epilepsy.

Pneumonia Migrans.

Dr. Victoria J. Antuszewicz, house-physician to the Zemsky Hospital in Orlov, Viatka Government, describes (*Proceedings of the Viatka Med. Society*, No. 2–6, 1886, p. 1,) two cases of so-called "wandering" or "migrating pneumonia" (as is known under the name of "pneumonia migrans," Waldenburg, Weigand, Fischl, Friedreich, Koranyi, Kelemen, and others, have described cases of croupous pneumonia, where the inflammation, having run its course at a given portion of the lung, appears at or—*sit venia verbo*—skips to another more or less *remote* pulmonary region; then, after resolution, the process originates at a third spot, etc.) One of her cases refers to a weak, emaciated, and exhausted woman, aged 38, in whom, a few months after her recovery from protracted granular endometritis, with severe flooding, there developed itself asthenic croupous pneumonia of the middle and lower lobes of the right lung. In the morning of the sixth day the temperature fell from 40.3° C. to 38.6° C., and the local symptoms seem to point to resolution. But in the evening the temperature rose again, and on the seventh day the upper lobe of the same lung became infiltrated in such a way that "between the old diseased portion and the newly affected one there remained only a zone of healthy tissue, measuring about two and a half fingers in breadth." On the tenth day normal vesicular breathing was heard over the middle and lower lobes, and on the eleventh day a second crisis followed. On the twelfth day collapse occurred, while the middle and lower lobes of the same lung again became engorged. On the sixteenth day the patient died "from cardiac and respiratory paralysis." (Unfortunately no necropsy was made to verify these statements.) Another case ended in recovery. The patient, an undersized, anæmic woman, aged 27, was attacked by pneumonia of the lower lobe on both sides. Resolution took place only on the eleventh day. On the twenty-third day there appeared rigor, rise of the temperature to 40° C., and infiltration of the superior lobe on both sides. On the thirty-second day a new crisis occurred, the patient leaving the hospital several days later, fairly well. Dr. Antuszewicz mentions also a third case of wandering pneumonia, which she happened to observe during her student days, and which ended fatally, the patient being simultaneously attacked with petechial typhus.

Dialyzed Pitch.

The *Druggists' Journal* says that the healing properties of vegetable resins are well known, and extracts therefrom have been used from time immemorial. The offensive character of the crude product has rendered its general use in medicine quite impracticable, however. A means of its purification by dialysis has been suggested by Mr. Charles J. Ulrici, a chemist of Havana, Cuba. The pitch is at first filtered to remove coarser impurities. The heat used in filtration serves to drive off certain objectionable volatile products at the same time. By dialysis, certain aldehydes, acetones, cyanides, benzoines, pyroligneous acid, formic acid, etc., are capable of being removed by dialysis when saturated with sodium bicarbonate.

The dialyzation is contined until the dialyzate (?) ceases to give efflorescence on the addition of H_2SO_4 the distilled water is renewed repeatedly until such reaction disappears. The remaining dialyzate (?) in the dialyzer consists of a neutral solution of colloidal and chemical nature, derived from the useful principles or components of the pitch. The dialyzed pitch is then subjected to heat and evaporated slowly, mixed with coarse sand, and continue the heat to evaporate more moisture, cool, and place in a lixiviating apparatus.

The soluble portion is then extracted by means of alcohol and glycerine, and a sort of fluid extract prepared. It is stated by the *Scientific American* that it has great medicinal value in the treatment of bronchitis, of throat disease, of ulcers, herpes, chronic rheumatism, and skin diseases.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

THE MORBID SEAT IN EPILEPSY.

Although it is generally acknowledged that the centre for convulsions resides in the medulla oblongata immediately above that of the centre for respiration, the original points of irritation, where the epileptic seizures originate, had never been fully determined. In a dissertation in Dorpat, May, 1886, Dr. H. Johannson mentions the results of experiments which he has made on 24 dogs, for the purpose of discovering the relation of the cortex and of other parts of the brain to epilepsy. He arrived at the following conclusions:

Typical epileptic attacks may be produced not only from the anterior but also from the posterior portion of the cerebral cortex, but from the latter *only* with *strong* electrical currents. The irritation is transferred from the posterior to the anterior portion; and not only by way of the cortical, but also by that of the white tissue, although the latter does not conduct so well, especially in narcotized animals. Both cortical motor centres need not be intact for the production of complete, double-sided seizures. Ablation of the motor centre during the acme of an epileptic seizure does not interrupt the spasm of the muscles of the opposite side, but the convulsions remain double-sided. After removal of the cortex of the convex surface of both hemispheres no irritation of the white substance will cause epileptiform convulsions. By irritating the lenticular body after destruction of the cortex, epileptic seizures may still be produced; also from the nucleus caudatus, but the latter stands in the same relation to the nucleus lenticularis, as the posterior portion of the cortex does to the anterior: it requires strong currents. J. also succeeded by electrical irritation of the peduncles of the cerebrum, especially of its basilar portion, in producing epileptic convulsions; but no irritation of the optic thalami gave any but a negative result.

A CASE OF HYSTERICAL MONOPLEGIA IN THE MALE.

A driver, æt. 25, belonging to a family with a decided neuropathic tendency, fell from a considerable height on his right shoulder. Four days later he suffered with complete palsy of the right arm, and anæsthesia from the shoulder-joint to the wrist, but palmar and dorsal surface of hand showed no sensory disturbances. Though the palsy had existed for fully five months, no contracture nor atrophy could be noted. Electrical reaction was also normal.

Drs. M. Marie and G. Guinon, who report the case in the *Progrés Méd.*, 1886, Nos. 34 to 37, incline to the belief that the paralysis was not of a traumatic but of a hysterical nature, especially as later other hysterical symptoms became added, as narrowing of vision, muscular polyopia, etc.

Considering the complete paralysis, we doubt its being of hysterical origin. We rather suppose that in consequence of the severe fall the hereditary tendency became later developed and then made its appearance. The palsy attacked the right arm; this in a laborer is generally far more muscular and more voluminous than the left, so that any atrophy which does not make a too rapid progress would probably not be observed very early. Contractures need not appear in these cases. Another reason for our view is the want of success of the treatment based upon the supposition of hysteria.

VASO-MOTOR NEUROSIS.

Dr. Leonard, in the *L' Encéphale*, 1886, No. 5, describes the case of a girl, æt. 19, in whom on various symmetrical parts of the body an erythema repeatedly made its appearance, which set in with high fever, 104½°, and which ceased again of its own accord after from two to four hours' duration. She also suffered at the same time, and not only during the attacks, but also, though not severely, during the intervening time, from epigastric pains, vomiting, and a decided diminution of the amount of urine excreted. There were, however, no motor or sensory disturbances; only three contractures were observed, with some mild sensory disturbances.

There was no indication of hysteria being present, but the general grouping of the symptoms was to L. an evidence of the vaso-motor nature of the erythema.

The case is in so far of great importance, as a physician who would see such a case during the first attack of this curious malady, might easily be induced to look upon it as one of erysipelas, or of some other grave exanthem. Certainly the periodicity, when once established, would easily lead to the correct diagnosis. A general tonic treatment, to which quinine in larger doses had been added, seemed to give the best results.

REMOVAL OF OVARIES IN FIBRO-MYOMA.

Dr. Duplay, in the *Arch. Gén. de Méd.*, 1886, June, reports two cases where, in consequence of uncontrollable menorrhagia due to uterine fibro-myoma, the ovaries were successfully removed. Based upon these observations and upon all the cases reported in literature and compiled for the Congress at Copenhagen, D. arrives at the following conclusion:

1. The removal of both ovaries is a remarkable success in severe metrorrhagia caused by uterine fibroids.

2. Notwithstanding the comparatively small mortality (14 per cent.), this operation ought to be performed only after all other milder means have been exhausted.

3. The operation is specially indicated in fibro-myoma of small and in those of moderate size, whose removal would be difficult or impossible, if not dangerous to life.

4. Whenever these conditions are obeyed, castration results almost invariably in the cessation of the hemorrhage, and also often in a diminution of the size of the tumors.

5. Castration is contra-indicated in large and cystic myoma, which are to be removed only by hysterectomy.

6. The operation must be performed on both sides; the extirpation of the free end of the tubes is also to be recommended, as otherwise they would suppurate, and only produce irritation in the wound.

HEREDITARY SYPHILITIC DISEASE OF THE GALL-DUCTS.

In a three-weeks'-old child, that from its birth had been suffering from a luetic skin eruption and from a severe icterus, but that from its birth had never presented any gastric symptoms, after death hard foci of the size of a hazel-nut were found in the lungs. On cross-section they were seen to contain a grayish-white gummatous mass. In the hilus of the intensely yellowish-colored liver a thick whitish new growth was found, which extended for some distance into the liver, and occupied mostly the gall-ducts. It extended outwards along the ductus choledochus communis into the gall-bladder. In the stomach a few hardened patches were met with, all of them presenting the same histological elements as are characteristic of luetic neoplasms. Some of them were also found in the mucous membrane of the alimentary canal. It was interesting to observe in some of them a retrograde formation due to the inunctions with ungt. hydrargyri, and they proved that the child's life might have been saved if the mother had been subjected to the same treatment while still being pregnant.

Notes and Comments.

Treatment of Serous Pleuritic Effusions.

Recently several authors have given it as their opinion that thoracentesis should be made in cases of pleuritic effusions only when the dyspnœa is so great as to necessitate the withdrawal of the accumulated fluid. Various methods were proposed to take the place of aspiration, and now Dr. J. Glax (*Ztschr. f. Klin. Med.*, ix., p. 471), recommends the therapeutical procedure practiced for years in Koerner's clinic, and which gave him a successful result in twenty-five cases, twelve of which concerned large effusions.

This method is based upon the withdrawal of all fluid nourishment, not as rigorously carried out as it formerly used to be, but in a more limited manner. The fluid ingesta are gradually reduced in quantity until the amount of urine excreted is equivalent to one-half, or still better, to two-thirds of the amount of fluid introduced into the organism—about the normal relation observed in health. As the diuresis is very moderate in cases of pleuritic exudations, one can easily see that the amount of fluid allowed to be taken in form of food must also be but a limited one; but to make the thirst less intolerable the limitation specially affects warm fluids, as soups, sauces, etc. Besides easily absorbable salts, especially chloride of sodium are administered, that they may pass with the blood into the pleuritic effusion, where they cause an absorption of fluid and its excretion by the urine.

Under this method of treatment G. observed a complete recovery in all of the twelve cases above referred to. The cure necessitated, on the average, thirty days, while the average duration of a great number of published cases of pleuritic serous effusions treated by aspiration amounted to forty-seven days.

As the treatment of pleuritic effusions does not seem a very successful one in our country, to judge from the number of deaths from this disease weekly reported in our large cities, the method above described may well merit a more extended trial.

Gonorrhœa in Women.

Dr. Lomer has published the results of a systematic examination of the vaginal secretion in several hundred women in Professor Schröder's wards. Bumm has recently insisted upon regarding the cervix uteri as the true seat of gonorrhœa, the vaginitis being a secondary result due to irritation from the cervical discharge. Neisser's diplococci are not easy to find in vaginal discharges, and are sometimes found in pus-cells in non-specific vaginitis. Dr. Lomer confirms the opinion that the vaginal discharge is unfavorable for the detection of diplococci, which should be sought in mucus taken direct from the cervix. Still, the same germs may be found in vaginitis in children and in women in childbed. Clinical appearances aid in the diagnosis of gonorrhœa, especially signs of inflammation of the vulva, urethra, and vagina. A greenish coloration of the pus in purulent catarrh of the cervix, Dr. Lomer, like other observers, considers to be suspicious. Sterility was very frequent in his cases of chronic gonorrhœa, and scanty menstruation was a very common complication. The existence of hydrosalpinx or pyosalpinx is of great diagnostic importance. A very considerable proportion of women in gynæcological departments of hospitals are subject to chronic gonorrhœa, without being aware of the fact. After the puerperium, gonorrhœa is the most frequent cause of uterine disease. Sanger traced gonorrhœa as the origin of disease in one-ninth of all his gynæcological cases.

Treatment of Severe Cases of Burning by Hebra's Water-bed.

In the *Glasgow Med. Jour.*, Dr. W. T. Laurie has a short article calling attention to the value of Hebra's water-bed in the treatment of severe burns and other extensive skin wounds from whatever source, and pointing out the advantages it possesses over the ordinary treatment by dressings. Hebra's water-bed, according to the description quoted from Kaposi, consists of an iron framework in the form of a bed suspended by chains in a zinc trough, and carrying a mattress on which the patient is laid. When in use, the trough is filled with warm water, and the patient is gently lowered into it, so as to be entirely immersed, excepting, of course, the head. The temperature of the water is then adjusted to his comfort, and it seems the best temperature is about 104° F. He is kept constantly in the bath, leaving it for functional purposes only, till the wounds have sufficiently healed to allow him to leave it for good.

The advantages claimed for the water-bed are:

1. That it abolishes pain and the consequent need for opium.

2. It does away with the torture and danger of repeated dressings.

3. It provides perfect facility for the removal of discharges, and is absolutely aseptic.

Climacteric Diabetes in Women.

We have before had occasion to call attention to the fact that in women this disease very frequently makes itself first manifest about the menopause. Mr. Lawson Tait has contributed an article on the subject to the *Practitioner*, and we give his closing words: "Roughly speaking, the conclusions that I have arrived at concerning this affection are that in the great majority of cases of eczema of the vulva at the climacteric period, the disease is due to the presence of sugar in the urine. I have not yet come across a case of this kind in which, having examined for sugar, I have not found it. The disease seems to begin at or near the arrest of the menstrual function, and to extend over a period of several years, then terminating in all probability by nature's own process. The sufferings of the patient are very much diminished, and probably the duration of the disease is shortened, by the liberal administration of opium; whilst the local trouble is best mitigated by ointments containing such substances as will arrest the process of fermentative change in sugar. So far the best substance that I have found for the purpose is the old-fashioned hepar sulphuris."

Etherization by the Rectum; Report of Four Cases by Yversen's Method.

After reporting four cases before the Philadelphia County Medical Society, Dr. John S. Miller concludes that in this method of etherization the most obvious advantages are as follows:

1. Dyspnœa is avoided, and the patient is saved from the anxiety due to a sense of impending suffocation.

2. There is avoided the danger of simultaneous irritation of the superior laryngeal and pneumogastric nerves at the periphery—these irritations neutralizing each other in the respiratory centre, and suspending respiration entirely.

3. The danger of asphyxia is lessened—the patient not being drowned in his own mucus, and the integrity of the pulmonary mucous membrane as an organ of gas exchange is preserved. Of course some vapor finds itself in the lungs, and acts there as a local irritant—elimination being by that channel, but the quantity is not great, and does not constitute a source of danger. In the cases reported the increase in secretion was too trifling for discovery.

4. The stage of excitation is therefore not prolonged by the struggles for breath. In general it may be said that the delirium of any alcoholic intoxication is a pleasant and good-natured one, unless the patient is crossed—as he certainly feels himself to be when a wet towel is pressed over his face.

Sudden Death Following Excision of the Uvula.

Dr. W. W. Tompkins, of Charleston, W. Va., reports in the *Med. Record* the case of a negro, thirty years of age, who asked his advice on account of a constant tickling in the throat and slight difficulty in breathing. Examination showed the uvula greatly elongated and projecting down below the base of the tongue. Its removal was advised, but the patient said he was afraid of an operation, and accordingly a gargle was prescribed; later in the day, however, the patient sent for Dr. Tompkins, and requested him to cut off the uvula. A small portion was accordingly removed, and the patient expressed himself as feeling better. In a few minutes the man's room-mate ran into the doctor's office and said the patient had dropped dead. There had been but little hemorrhage, and the operation had seemed to relieve the symptoms. But the patient had, on the occasion of his first visit, said that he had heart disease, although, as he was wet and dirty, having worked at ditching all night, no physical examination was made. Dr. Tompkins had thought of giving ether, as the patient was so nervous and fearful, but congratulated himself afterward on not having done so. Death was evidently due to cardiac disease, the immediate cause probably being the excitement caused by the operation. The patient's father had dropped dead under somewhat similar circumstances three years before.

At What Part of the Intestinal Canal Do its Contents Become Feculent?

While we cannot say that any very weighty practical questions rest upon the solution of this problem, yet, as a matter of information, we note the following conclusion of a paper by Dr. E. G. Waters in the *Maryland Med. Jour.*, June 26:

"Now, the sum of this whole matter is this, that here, as in so many departments of physical study, our ignorance is humiliating, after the immense time and labor given to the subject by able and conscientious men

who were and are not mere makers of books. Nevertheless, the weight of evidence is largely in favor of the supposition that the contents of the small intestine before they are pushed beyond the ileo-cæcal valve are probably, as a rule, wanting in no feculent feature, unless it be that of mere solidity. If the contents of the small intestine are not excrementitious, how is it that in stercoraceous vomiting such matters are brought up, if, as some experimentists tell us, the ileo-cœcal valve is impervious to the return even of liquids from beyond it? And if the chief office of the colon is absorption, according to Foster, how does so considerable an accumulation of feculent matter take place in it, when we remember that Berzelius estimates the residue from food at less than 33 per cent. of the entire mass? To these and other similar questions it seems to me there can be but one answer."

Catheter Fever.

Dr. W. Hutson Ford thus concludes a paper in the *St. Louis Courier of Medicine* for June:

The irritating agency in such cases is, I believe, mainly the unremitted catheterism, for I have found puncturing the bladder by the rectum, with a discontinuance of the catheterism, to be followed by speedy amendment. But the concurrent decomposition of the urine must also be regarded as a prime source of irritation, and the absorption of such tainted urine, through surfaces abraded by the catheter, must be considered as the direct cause of the septicæmic elements of the fever. A degree of uræmia also plainly concurs, which increases to a lethal extent in fatal cases, and this would first be due, I imagine, to the establishment of latent nephritis, as it is not a primary condition. Such a nephritis may be looked upon as a pathological accompaniment of the subacute septicæmia, specially, perhaps, determined to the kidneys by the sympathetic relations of the bladder, and particularly of the deep urethra, to those organs.

Large Doses of Digitalis in Pneumonia.

In a Roumanian medical journal, *Spitalul*, February, 1886, Dr. I. Antoniu, of the Military Central Hospital in Bucharest, describes an interesting case of a weak soldier, aged 23, who was admitted to Professor Z. Petrescu's wards about twenty-four hours after an initial severe rigor, with grave (*forte alarmâtóre*) general and local symptoms of pneumonia. At once an infusion of digitalis (four grammes of the leaves to 200 grammes of water, the whole to be taken in frequent doses during the day) was given. The same treatment was pursued during the next day (the third of the disease). On the morning of the fourth day the temperature suddenly fell from 39°.5 C. to 36°.3 C., and the pulse from 92 to 60 a minute. On the fifth, the temperature was oscillating between 36.3° and 37°, a marked amelioration in the local symptoms being observed. On the sixth, the patient's general state was quite satisfactory. On the tenth, he was practically well, but was retained under observation for another eight days. For several days the pulse continued to be as slow as 44 to 48 a minute, it being still 52 twelve days after the last (second) dose of the drug.

The Universality of Syphilis.

It would seem that no part of the body is secure from the ravages of this disease. That there are many instances of seemingly strange departures from health that are to be accounted for by the syphilitic poison there can be no doubt. Now, in *Schmidt's Jahrbücher*, Dr. L. Galliard reports some cases of gastric trouble successfully treated with mercury and iodine, and recalls two instances in which Klebs and Cornil found gummy tumors in the wall of the stomach. He concludes that there exists a syphilitic disease of the gastric mucous membrane, which consists in the presence of ulcerated gummata of the wall of this viscus. This gastric syphilis would seem to be less uncommon than has hitherto been supposed, and the author believes that many cases of alleged simple ulcer occurring in syphilitic patients are really referable to the action of the specific virus, and that much good would result from specific treatment in such cases.

Treatment of Facial Neuralgia by Cocaine.

Dr. de Coninck, of Ledeberg-les-Gant, writes to the *Scalpel*, of Liège, that the effects of hydrochlorate of cocaine in facial neuralgia and in cephalalgia having its seat in the temporal region are surprising. The pain, be it ever so intense, will instantaneously cease on applying to the auditory canal one minim of a solution of one per cent. of this salt, by means of a small camel-hair brush. This signal effect, however, will only continue for a few hours, after which a repeated application may be required. Hydrochlorate of cocaine has never failed in the many

cases of these kinds of neuralgia, treated in that manner by Dr. de Coninck. In neuralgia of the fifth nerve and its branches, however, the results were less certain and less satisfactory, owing, perhaps, to the superficial mode of its employment.

Trypsin in Diphtheria.

Trypsin has been employed of late in the treatment of diphtheria for the purpose of dissolving the exudation membranes, over which it appears to possess no inconsiderable solvent powers. According to Dr. Saunders, of St. Louis, Mo., it invariably cleared off the membranes in sight in less than a day, and even in cases which terminated fatally, it certainly appeared to delay the fatal issue. It does not, of course, relieve the œdema which precedes and accompanies diphtheritic exudation, and for obvious reasons cannot be thoroughly applied to the larynx. Apparently we have here an agent which gives promise of great usefulness in some of the worst types of diphtheria and membranous croup. A good strength to use is thirty grains to the fluid ounce of water, with ten grains of bicarbonate of soda. This solution should be applied over the parts every half hour until the membrane disappears.

Aneurism of the Subclavian Artery Cured by Galvano Puncture.

Dr. Saboia has presented to the Imperial Academy of Medicine of Brazil the history of a case of aneurism of the right subclavian artery in a young man aged 30, cured by galvano puncture. The tumor was of the size of a small hen's egg, bounded on the inner side by the sterno-mastoid, below by the clavicle, and on the outside by the trapezius. There was no difference between the pulsations of the two carotids, but the radial pulse of the left side was strong, full, and vibrating, while on the right side it was small, filiform, and scarcely perceptible. Two metallic needles were introduced into the tumor, and connected with the positive pole of a Gaiffe's pile of fourteen elements, the negative pole being applied to the trunk at a distance from the aneurism. The sitting lasted thirty-five minutes, at the end of which the tumor had become tense and had ceased to pulsate.

Hæmoptysis as a Symptom of Pneumonia.

In the *Lancet*, June 19, Dr. D. W. C. Hood publishes a paper in which he emphasizes the fact that in certain pneumonic conditions a sharp hemorrhage at the initial stage is symptomatic of the attack, and is, as he believes, directly caused by the inflammatory hyperæmia. In such cases, where a severe hemorrhage ushers in the attack, we shall find the inflammatory focus very frequently at one or other apex, and the physical symptoms of such a pneumonia are often more easily demonstrated at the posterior than at the anterior region of the chest. Such pneumonia, complicated with severe hemorrhage, is peculiarly connected with lung tissue already the seat of chronic change, whether such change be due to deposition of tubercle or to chronic inflammatory changes.

Examining the Urethra.

Dr. W. B. Rogers very truly says, in the *Mississippi Valley Med. Mo.*, for June, that much harm may be done locally in a urethral examination, and even death has followed the introduction of a sound where no violence was used. Bear these points foremost in your minds, and conduct your examination with the utmost care—do no violence whatever in your *examinations*. Never pass an instrument into the urethra of a patient not in the recumbent position. It is a good rule to see that the urine of the patient is bland and unirritating, and to this end, when practicable, administer alkalies for some hours before the examination. Inject the urethra with oil; it is far better than simply oiling the instrument. In cold weather have the instrument warmed to a comfortable temperature.

A New Method of Treating Throracic Aneurism.

Under this title Dr. Richard Barwell describes a method which he has recently employed. It consists in puncturing the sac with a hollow ivory needle, and passing through this and into the sac about ten feet of fine steel wire. This latter is connected with a galvanic battery (positive pole), and a current of nine or ten milliampères is passed through it for an hour. In the case in which this method was tried a considerable degree of firm coagulation was obtained, but the aneurism had a second sac, and the patient was nearly moribund before the operation. He died a week later.

The Vomiting of Pregnancy.

Dr. C. H. Hollady thus writes in the *Medical Age:*

To sum the whole up, I have come to the conclusion, as before stated, that the gastric

trouble is sympathetic in its nature, and depends upon reflex nervous irritation; that this irritation has its origin in the ovary, and is the result of the increased growth and development of the true corpus luteum; and that in complicated cases, in proportion to the degree of development to which the body attains and the length of time that elapses before its retrograde changes begin to take place, will be the prominence and duration of the annoying symptom.

Atrophy of the Left Arm, the Result of Cellulitis.

Mr. A. G. Miller presented this case to the Medico-Chirurgical Society of Edinburgh, June 2. The appearance presented was literally that of skin and bone, from the shoulder downwards. The atrophy was most complete on the extensor aspect. There was complete anchylosis at the elbow, and an approach to the same condition at the wrist. The etiology of the affection was doubtful. In connection with the case, Dr. Byrom Bramwell exhibited a photograph, recently taken, of a patient under treatment for phthisis, showing atrophy limited to the muscles of the shoulder and upper arm.

Obstinate Vomiting.

A valuable hint may possibly be derived from the following closing paragraph of Dr. E. Chenery's article in the *New England Med. Monthly*, June 15:

"I here raise the question: Are not many of our obstinate cases of vomiting, particularly in pregnancy, wholly dependent upon inaction of the upper part of the small intestines whereby the alkaline bile is sent back into the neutral or acid stomach, disturbing its function and causing irritation, muscular contraction, and ultimately inflammation of the organ? If so, the way is plain by which to bring relief."

Nitrite of Amyl in the Paroxysms of Whooping Cough.

Dr. Morris Lewis has been unable to find anything in medical literature on this subject, and he therefore reports, as original, to the Philadelphia Neurological Society, his case of a female infant thirteen weeks old wherein this remedy controlled the violence of the paroxysms. A mixture of ether and nitrite of amyl (one-fourth part of the latter) was kept in a vial, and with each paroxysm of cough the end of the finger was wetted with the mixture and held close to the child's nose and mouth, so as to catch the first inratory effort.

A Novel Method of Treating Hysteria.

The *N. Y. Med. Jour.* tells us that Rualt (*France Médicale*) affirms that he has frequently controlled an hysterical fit by making firm pressure with the thumbs on the supra-orbital nerves at the supra-orbital foramina. The patients are described as first contracting the facial muscles as if in pain; they then cry out and take several inspirations, followed by a long expiration. They now relax their muscles, and the convulsion is at an end. Pressure should not be maintained after this, lest another attack be excited.

Cocaine as a Diuretic.

It is a wonder that the nostrum venders have not created a great demand for this drug, for surely it seems as though there is no therapeutic virtue that it does not possess. Now, no less an authority than Dr. J. M. Da Costa tells us, in the *Med. News* (June 18), that it has a decided diuretic action, and in uræmia, with scanty secretion of urine, it should be tried. It would truly seem that there is no end to the virtues of this drug.

News and Miscellany.

Tricks in the Microscope Business.

Dr. James, President of the St. Louis Society of Microscopists, thus exposes in the *Scientific American* a trick adopted by the vendors of cheap microscopes. They use a small particle of sour paste, pretending it is a drop of water, and the objects shown are *anguilulæ*, or paste eels. The following is the method of working the trick:

The vendor has standing before him on the stand with his instruments a glass or clear water, usually containing a bit of ice. On a little bench under the table, and concealed from public view, there is a small box of sour paste, plentifully supplied with anguilulæ.

When a customer steps up, the chances are a hundred to one, as every microscopist knows, that his first question will be, "Does this here show the animalcules in water?" The ready answer is, "Show 'em? Certainly! Fact is, I don't dare to look at the water. I keep melted ice water for my use. That generally ain't got many." "Has that water

got any in it?" continues the querist. "We can see," says the vendor, and he picks up a clean toothpick, dips it into the glass, and prepares to put a drop on the front lens. His hand, however, is shaky, and the toothpick drops, falling generally on the little shelf which projects slightly from under the table. He picks it up again, and under pretence of wiping it, sticks it into the paste, gets a very minute particle to adhere, again touches it to the water, and smears the front of the field or objective lens.

The victim then looks, and is amazed and delighted, and straightway invests in a 'scope, paying from one to two dollars for what costs the vendor less than fifteen cents ($1.75 per dozen).

This ingenious piece of rascality was the invention of a man who formerly made his headquarters in Pittsburgh, Pa., and who for years has derived a large revenue from this and similar "fakes" got up for the use of street vendors, who either pay him a royalty on their use or buy outright the privilege of using them. I was told by three different individuals that they paid this man fifty dollars each for the secret of this "fake," but that, not being able always to find paste which contained eels, they were also compelled to purchase from him at a large price some "starting" or cultivating fluid. All sour paste does not contain the anguilulæ; vinegar eels are sometimes used, but only when the cultivated paste eels cannot be got, as they are too large—one of them frequently stretching entirely across the field of vision. The eels raised in paste without the use of this fertilizing fluid are much larger than those obtained by its aid.

The number of educated people who are caught by this trick is really astonishing to one who habitually uses the microscope. A street vendor here tells me that he has repeatedly sold 'scopes to physicians whom he had fooled into believing that the instruments possessed amplifying power sufficient to enable them to distinguish blood and pus corpuscles, and even bacteria.

A Chinaman on Tea Making.

Wong Chin says, in *The Cook*, in regard to preparing tea: "Use a china or porcelain pot. If you do use metal, let it be tin, new, bright, and clean; never use it when the tin is worn out and the iron exposed. If you do, you are playing chemist and forming a tannate or tea-ate of iron. Use black tea. Green tea, when good, is kept at home. What goes abroad is bad, very bad, and horrible. Besides containing the 203 adulterations the Chinese philanthropist puts up for the outside barbarian, it is always pervaded by copper dust from the dirty curing-pans of the growers. Infuse your tea. Don't boil it! Place one teaspoonful of tea in the pot and pour over it one and a half cups of boiling water, that is, water really boiling. If your tea is poor, use more. It is cheaper, though, to buy good tea at the outset. Put your pot on the back part of the stove, carefully covered, so that it shall not lose its heat, and the tea its bouquet. Let it remain there five minutes. Then drink it. Drink your tea plain. Don't add milk or sugar:—tea brokers and tea tasters never do; epicures never do; the Chinese never do. Milk contains fibrin, albumen, or some other such stuff, and the tea a delicate amount of tannin. Mixing the two makes the liquid turbid. This turbidity, if I remember the cyclopædia aright, is tannate of fibrin, or leather. People who put milk in tea are, therefore, drinking boots and shoes in mild disguise."

Astley Cooper Prize.

It is announced that the next triennial prize of £300, under the will of the late Sir Astley P. Cooper, Bart., will be awarded, early in 1889, to the author of the best essay or treatise on "The Origin, Anatomy, Results, and Treatment of Tubercular Diseases of Bones and Joints." The conditions annexed by the testator are, that the essays shall contain original experiments and observations which shall not have been previously published; and that each essay shall (as far as the subject shall admit of) be illustrated by preparations and drawings, which shall be added to the Museum of Guy's Hospital, and shall, together with the work itself, become henceforth the property of that institution. And it is especially declared in the will that no physician or surgeon or other officer of Guy's or St. Thomas' Hospital, nor any person related by blood or affinity to any officer in either of the said hospitals, shall at any time receive or be entitled to claim the prize. But, with the exceptions here referred to, this prize is open for competition to the whole world, though the essay may not be the joint production of two or more authors.

The Leper Hospital at Bergen.

In a foreign exchange is a description, by Mrs. Charles Garnett, of the Asylum for Lepers at Bergen, the largest of the three

institutions of the kind in Norway. Together they are capable of accommodating 800 patients, the number of inmates in 1880 being 617. The poor sufferers seem to be well cared for, and their lives made as pleasant by cheerful surroundings as their pitiable condition will admit of. Some of the rooms visited by the writer, however, were rendered intolerable by the want of ventilation, to which the lepers appear to have a deadly antipathy. In vain do the doctors in the morning throw open the windows; they are again closed as soon as opportunity offers. Most of the patients find a measure of relief from the monotony of their dreary existence by engaging in some kind of handicraft in the large workrooms set apart for the purpose. Segregation being recognized as the only effectual means of lessening the prevalence of leprosy, and of finally annihilating it, the Norwegian government, we are told, is seeking to obtain powers to make the isolation of the sick compulsory, either in the national asylums or in their own homes.

Doctors' Door-keepers.

We must confess to a strong persuasion that, as a rule, it is better for a "doctor's koor-keeper" to be a male than a female. An exception may be made in favor of women servants in attendance at the houses of certain specialists—for example, the gynecologists; but, speaking generally, we think it is more decorous that the door should be opened by a man than by a woman, looking to the mixed character of the gathering in most waiting-rooms, and the service which has not unfrequently to be rendered to those who are infirm or weakly. As to the idea put forth by a contemporary that doctors' door-keepers are "got up" to look impressive, that, of course, is absurd. Opening the door to a considerable number of sickly-looking folk, for the most part accompanied by friends with anxious countenances, is not an inspiriting occupation, and it is scarcely to be expected that the doctor's door-keeper will wear a particularly jovial expression, but it should suffice that he is respectful, self-possessed, and well-behaved, and if these qualities can be secured, both doctor and patient may be well satisfied.

Lady Doctors in the Fifteenth Century.

Dr. Horowitz, of Frankfort-on-the-Main, has (*The Jewish Chronicle*, May 14, 1884,) published a work, entitled *Jüdische Aerzte in Frankfürt*, in which the learned author mentions the interesting fact that, as long as four hundred and fifty years ago, Jewesses practiced medicine in that city; they especially devoted themselves to ophthalmia. The female oculist, Dr. Zerlin, whom we meet with in the volume as having practiced in the year 1428, ventured to reside outside the Judengasse, and believed that she could claim exemption from the payment of taxes on account of her talent and the general esteem in which she was held. The Municipal Council rejected her application, and, in 1489, they ordered that Jewish lady doctors should either quit the city or pay taxes like other Jews. A Jewish doctress was, however, more fortunate in the year 1494; she was relieved from the payment of "sleeping money," a tax imposed on foreign Jews for every day that they stayed in Frankfort. With this exemption was coupled an official recognition of her profession, which was of the utmost advantage to the lady.

New Hampshire Medical Society.

At the ninety-sixth annual meeting held at Concord, June 15, the following papers were read: "The Coming Physician," by Dr. George A. Crosby, of Manchester, N. H.; "School Hygiene," by Dr. D. M. Currier; "Report on Obstetrics," by Dr. Frank Blaisdell; "Medical Common Sense," by Dr. C. A. Allen; "Theory and Practice of Medicine," by Dr. J. F. Brown; "Report on Surgery," by Dr. C. B. Hammond; "Fashionable Follies," by Dr. M. H. Felt; "Typhoid Fever," by Dr. I. H. Adams; "Nerve Weakness," by Dr. H. C. Holbrook; "An Improved Method of Measuring the Chest," by Dr. Wilkins. The following officers were elected:

President—Prof. C. P. Frost, of Hanover.

Vice-President—Dr. S. W. Roberts, of Wakefield.

Treasurer—Dr. D. S. Adams, of Manchester.

Secretary—Dr. G. P. Conn, of Concord.

Anniversary Chairman—Dr. M. H. Felt, of Hillsborough Bridge.

The Consumption of Tea.

According to some statistics recently published by an Indian contemporary, it appears that the people of Great Britain are considerably behind other nations in the average consumption of tea per head of population. The Australians come first with 7.66 lb. per head; the New Zealanders next with 7.23 lb. per head; while the people of Great Britain,

though appearing third in the list, consume only 4.90 lb. each. Newfoundland and Canada come next, while in the United States the consumption is only 1.30 lb. per head; and in Russia, which is always regarded as a great tea-drinking country, the consumption is only 0.6 lb. per head. Belgium, Sweden, Austria-Hungary, and Spain, consume less than the other European nations; but there is not one nation on the Continent, with the exception of Holland, in which the annual consumption exceeds 1 lb. per head.

Strange Prescription.

A Scotch lad was on one occasion accused of stealing some articles from a doctor's shop. The judge was much struck with his respectable appearance, and asked him why he was guilty of such a contemptible act. "Weel, ye see," replied the prisoner, "I had a bit pain in my side, and my mither tauld me tae gang tae the doctor's and tak' something." "Oh, yes!" said the judge. "But surely she didn't tell you to go and take an eight-day clock?" The prisoner was evidently nonplussed, but it was only for a moment. Turning to the judge, a bright smile of humor stealing over his countenance, he rejoined quietly, "There's an auld proverb that says, 'Time an' the doctor cure a' diseases,' and sae I thocht"—but the remainder of the reply was lost in the laughter of the court.

European Capitals and Their Water-supply.

Rome heads the list with her 204,000,000 litres of pure water every twenty-four hours. Her population being 345,036, every inhabitant can dispose of 591 litres per diem. London comes next, for every one of whose 4,085,040 inhabitants there are 300 litres daily. Paris takes the third place, her population amounting to 2,240,124, and each inhabitant having for alimentary uses 58 litres per diem, and for secondary purposes 169—a total of 227 litres. Berlin has 1,302,283 inhabitants, for each of whom there are 140 litres daily, Vienna, 770,172 inhabitants, with 100 litres each per day; Naples, 463,172, with 200 litres; and Turin, 278,598, with 98 litres a head every twenty-hours.

Arsenical Wall-Papers Utilized.

Mr. Matthieu Williams has suggested that the arsenical wall-papers, which are generally regarded as detrimental to health in ordinary localities, may be useful as a protection against the dangers of regions subject to malaria. In a recent number of the *Gentleman's Magazine*, he says: "I maintain that the hotels in the vicinity of the Campagna, the Pontine Marshes, the Maremma, and other malarious regions of Italy, should be papered throughout with brilliant green arsenical papers, and painted with Scheele's green or other arsenical pigment. The same should be done in New Orleans and all other such places, for the special benefit of non-acclimatized visitors."

He Snatched Her from the Grave.

An old member of the medical profession in Chicago tells the *News*, of that city, a story which, he says, Dr. J. Adams Allen told him many years ago. Dr. Allen, as the story goes, was just beginning his practice when, one winter day, seated in a car, muffled to the ears, he heard the following conversation between two passengers who were sitting where they could not see his face: "Say, George," said one, "what kind of a doctor is this young Allen?" "All I know about him is that he snatched my aunt from the grave last summer; that is, I shall always think he did." "Did he, indeed," said the other; "well, he must be a pretty good doctor then. What was the matter with your aunt?" "Oh, she was dead and buried, you know."

Genius and Monomania.

Dr. H. C. Wood, in a recent clinical lecture on monomania, speaking of the relation between genius and this form of insanity, says: "One of the best examples of the relation between great imaginative power and monomania is John Bunyan, the author of 'The Pilgrim's Progress,' which, according to any standard that we have a right to set up, is one of the five or six greatest books in the English language. It is certainly more read than any other book, with the exception of the Bible. No one who reads the history of Bunyan's life can doubt for a moment that he suffered from monomania with depressing delusions. He, however, finally recovered."

Photographing the Uterine Cavity.

A Swiss physician describes a plan of introducing wadding tampons and laminaria tents into the uterus, by which he has succeeded in dilating the organ to such an extent as to be able, by means of reflectors, to

get a complete view of the whole cavity in cases of carcinoma, fibrous polypi, fibromata, and endometritis. Not being content with ocular inspection, he has also contrived to obtain photographs of the cavity. New inventions for uterine exploration, medication, and instrumentation, are often of a somewhat hazardous nature; but we tremble to think of the future of some female patients if photographing the interior of the uterus should ever become one of the medical fashions of the day.

A Bequest to Darwinism.

Herr Paul von Ritter, of Basle, has left to the University of Jena the sum of 300,000 marks (£15,000), the interest of which is to be applied solely to the promotion of the study of phylogenetic zoölogy according to the doctrines of Darwin, of which Professor Häckel, of the above-named university, is an able exponent. Of the above named sum, 130,000 marks are to be received at once, and the remainder on the death of the testator. Professor Häckel proposes to apply a portion of the money to the foundation of a new extraordinary professorship of zoölogy, to be called the Paul Ritter Professorship.

Furniture Polish.

Melt three or four pieces sandarac, each of the size of a walnut, add one pint of boiled oil, and boil together for one hour. While cooling, add one drachm of Venice turpentine, and if too thick, a little oil of turpentine also. Apply this all over the furniture, and, after some hours, rub it off; rub the furniture daily, without applying fresh varnish, except about once in two months. The *Scientific American*, which gives this formula, says water does not injure this polish, and any stain or scratch may be again covered, which cannot be done with French polish.

A Wonder Doctor.

A Dr. A. Askotchensky, of Verkhnedneprovsk, by permission of the local authorities, distributes a leaflet describing wonder-cures which he obtains from the internal administration of clay in cases of chronic rheumatism and other morbid forms depending upon rheumatic cachexia, as well as in cases of anæmia, where clay is more of use than all steel preparations. A solution (*sic*) of clay being injected into the vagina, cures catarrh of the latter. Of course, all those marvellous properties are manifested exclusively by the clay sold by the doctor.

Medical Jurisprudence and Biology.

At a recent meeting of the Paris Biological Society, M. Mégnin stated that zoölogical and botanical evidence enabled him to determine the length of time during which human bones had been buried at Villemouble. It will be remembered that Mllme. Menetiel was supposed to have been murdered and buried in her own garden in that place by Euphrasie Mercier; but the presence of ants' nests and deteriorated liliaceous bulbs proved, according to M. Mégnin, that the bones had been buried there for at least two years.

Scientific Journals in Japan.

A paragraph in *Nature* states that there are thirty-seven periodicals published in Japan, devoted to matters connected with education; of this number, seven are medical papers, with a monthly circulation of 13,514. There are nine papers relating to sanitary matters, and two to pharmacy. There are also nine other papers, devoted to other branches of science; and no fewer than twenty-nine papers, with a circulation of over 70,000, engaged in diseminating a knowledge of popular science.

Sudden Death from Grief and Fear.

A lady, named Madame Dumas, on receiving the sad news, recently, that her husband's body, found in the Rhône, had been taken to the Morgue, at Lyons, went to identify the corpse. The sight of it produced such a profound impression that she fainted, and died within a few minutes. There can be no doubt that the approximate cause of death was violent emotion, but it would have been interesting to know what visceral disease existed in the deceased.

Strange Cause of Mummification.

M. Brouardel has reported to the Paris Academy of Medicine upon the mummification of the body of a young woman which was found in a heap of straw in a cellar. The cellar had not been opened for eight months. The body was in a remarkable state of preservation. The mummification was due, according to MM. Brouardel and Mégnin, to myriads of acari of various kinds, whose eggs were embedded in the tissues.

A New Source of Brandy.

The *Chemist and Druggist* says that a new source of brandy is said to have been found by a botanist of Pondicherry, who has descovered that the pulp which covers the poppy seed contains saccharine matter which, after fermentation and distillation, produces a kind of spirit of brandy of an agreeable flavor. As this pulp has hitherto been thrown away, the discovery affords poppy planters an opportunity of realizing some more profit from their crops.

Wood Oil.

Wood oil is now made on a large scale in Sweden from the refuse of timber cuttings and forest cleanings, and from stumps and roots. Although it cannot well be burned in common lamps, on account of the excessive amount of carbon it contains, it furnishes a satisfactory light in lamps specially made for it, and in its natural state is the cheapest of all illuminating oils. Thirty factories produce about 40,000 litres of the oil daily.

The Capacity of Teaspoons.

A large number of teaspoons on being measured showed an average capacity, according to the *Western Druggist*, of 80 minims. A spoon which held 80 minims of water, when filled up to its edge, was found by actual experiment to hold 40 minims more of water, or 2 fluid drachms, without running over. This affords a good argument for the use of measuring glasses.

Items.

—Patient: "Well, doctor, what do you call it?" Doctor: "Progressive paralysis." Patient's wife: "Is it anything like progressive euchre, doctor?"

—A sanitary convention at Coldwater, Michigan, under the auspices of the State Board of Health, will be held on Thursday and Friday, September 23 and 24, 1886.

—Dr. Pierd'houy, oculist at Milan, considers that scopoleine has properties similar to those of atropine, but is preferable, because it produces neither redness nor irritation.

—We learn from the *Lyon Medical* that asparagus grown in certain localities becomes impregnated with minute amounts of sulphide of carbon. Persons eating this are affected with violent colic and diarrhœa.

—Prof. Bartholow speaks very favorably of the use of nitro-glycerine persistently in the treatment of *fatty heart*. It takes the strain off the weakened organ, and allows it to gain strength, while its work is lessened.

—The reports which appear from time to time of individuals who have lived to round out a century of existence have frequently been doubted by vital statisticians. In order to settle the question, Prof. Humphrey, of England, is now engaged in collecting and sifting these reports, and promises soon to publish those whose authenticity is undoubted.

—In the course of some excavations on the site of John Hunter's house, in London, recently demolished, the workmen discovered several human skulls, and a considerable number of bones of the extremities, sawn across, as though from limbs which had been amputated by the illustrious surgeon.

—The Washington correspondent of the *N. Y. Med. Jour.*, says that the President has vetoed the bill legalizing dissections in the District of Columbia, on the ground that the bill did not provide sufficient safeguards against the delivery of bodies to unauthorized persons. It is understood that the measure will be amended and reintroduced.

—The *Peoria Medical Monthly* says that the Dayton, Ohio, doctor, who has an office on a street leading to the cemetery, has a reversible sign on his front. Usually he has the side out on which is his name, but when a funeral passes he turns it over, and then the following legend is displayed: "Not My Patient; I cure every man that follows my directions."

—The deaths of children from sucking lucifer matches have of late years happily been decidedly unfrequent, but it appears that this form of poisoning is not quite obsolete. At an inquest lately held in England, the evidence showed that the deceased, a child of two years old, had been taken ill with vomiting after playing with some lucifer matches; death had ensued on the following day.

—A pale, cadaverous-looking Irishman entered a doctor's office, and with both hands pressing heavily his right chest, in much agitation, addressed the medical man, in a whisper, as follows: "Doctor, I'm in a very bad condition: my right lung is clean gone, and I have lost my voice entirely," then changing both hands to the opposite breast, he continued in a loud, clear voice, "but this lung is all right, doctor."

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

These which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

—ANTI-SEPTIC—

For Internal and External Use.

LISTERINE

LAMBERT

PHARMACAL COMPANY.

ST. LOUIS.

FORMULA.—Listerine is the essential Antiseptic constituent of Thyme, Eucalyptus Baptisia, Gaultheria, and Mentha Arvensis in combination. Each fluid drachm also contains two grains of refined and purified Benzoboracic Acid.

ANTISEPTIC, PROPHYLACTIC, DISINFECTANT, NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC, AGREEABLE, STRICTLY PROFESSIONAL and SCIENTIFIC.

LISTERINE comes nearer the ideal Antiseptic than any preparation now before the Medical World.

Send for New Formula Book and General Reports, establishing its value externally in SURGERY, OBSTETRICS, GYNECOLOGY, LEUCORRHŒA, GONORRHŒA, and all MUCOUS MEMBRANE DISEASES; internally in TYPHOID and other FEVERS, ZYMOTIC DISEASES DIPHTHERIA, SCARLET Fever, DYSPEPSIA, DYSENTERY, DIARRHŒA, all forms of CHOLERA, etc., and as a general PROPHYLACTIC

THE BEST

—ANTI-LITHIC—

For the Uric Acid Diathesis.

LITHIATED HYDRANGEA

LAMBERT

PHARMACAL COMPANY.

ST. LOUIS.

FORMULA.—Each fluid drachm of "Lithiated Hydrangea" represents thirty grs. of Fresh Hydrangea, and three grs. of Chemically Pure Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

KIDNEY-ALTERATIVE AND ANTI-LITHIC, RELIABLE, UNIFORM, AND DEFINITE.

The solution and elimination of an excess of uric acid and urates is best attained by an intelligent combination of certain forms of Lithia and a Kidney Alterative.

The ascertained value of Hydrangea in Calculous Complaints and Abnormal Conditions of the Kidneys through the earlier reports of Drs. Atlee, Horsley, Monkur, Butler, and others, and the well known utility of Lithia in the diseases of the uric acid diathesis, AT ONCE justified the therapeutic claims for Lambert's Lithiated Hydrangea when first announced to the Medical Profession, and it is now regarded by Physicians generally as the best and most soothing Kidney Alterative and Anti-lithic Agent yet known in the treatment of URINARY CALCULUS, GOUT, RHEUMATISM, BRIGHT'S DISEASE, DIABETES, CYSTITIS, HEMATURIA, ALBUMINURIA, and Vesical Irritations generally.

WOUND TREATMENT.*

BY A. S. V. MANSFELDE, M. D.,

Of Ashland, Neb.,

President of the Nebraska Railroad Surgeons' Society, Permanent Secretary of the Nebraska State Medical Society, etc:

Since what I will have to say is based upon Sir Joseph Lister's conception of asepticism, it may not be out of place here to state what I understand by asepticism, and its legitimate child, antiseptic surgery. Asepticism, as already stated, owes its existence as a means in surgery entirely and alone to Sir Joseph Lister. It comprises the idea that a wound shall not come in contact with anything, be its source whencesoever and its nature whatsoever, that may in any way interfere with the physiological repair of an injury. This comprises healing by primary union and primary adhesion, immaterial whether the *spray* and all the other paraphernalia once and now employed by Sir Joseph, come in contact with the wound or not. Antiseptic treatment of wounds includes all legitimate means—those of Sir Joseph and of every body else—which will secure to an unclean wound its pristine purity, and *maintain* it, until repair is complete. The excellency of the plan adopted to carry out to their fullest extent these methods of wound treatment must be sought for in the efficacy of the agent used to destroy or exclude the means of infection; in its non-irritating character, the facility with which it can be employed, and its non-interference with the patient's health.

For the purposes of this paper the following methods of treatment are adopted from a paper by Assistant Surgeon U. S. A., Henry Raymond, A. M., M. D.:

I. *Non-antiseptic occlusion*, by which is meant a healing of the wound under the simple blood-clot, scab, or crust without the intervention of surgical aid or appliance.

II. *Primary antiseptic occlusion, i. e.*, the immediate application (at the earliest possible moment) of an occlusive covering to the wound on antiseptic principles.

III. *Primary Antiseptic Drainage.*—This treatment includes the most scrupulous disinfection of a wound visibly contaminated, or specifically or septically infected from any cause whatsoever; the removal of all irritating secretions the very moment they are formed, through some provision of drainage, to make which complete it may be necessary to resort to extensive incisions, resections, and amputations, and finally an occlusive covering equal to that employed in primary antiseptic occlusion. Intermediate drainage, after the acute stage has passed, before the establishment of suppuration, and secondary drainage, resections, and amputations after the setting in of pus formation, are operative measures, which, as Dr. Raymond aptly puts it, "awaken in one's mind the consciousness of a lost or unheeded opportunity." These are measures very seldom necessary when all the details of primary antiseptic drainage and occlusion have been most carefully executed.

Whether or not it is safe to interfere with the blood-crust in the first category of wounds coming under the notice of surgeons, must

*An address before the Railroad Surgeons' Society of Nebraska, sent for publication by the author upon the request of the Society.

always be left to the judgment of the individual. The question he has to decide is not whether or not the blood-crust is a sufficient dressing, for such it has been too often to admit of controversy, but whether or not the wound underneath the crust is *aseptic.* If his answer be in the affirmative, then the crust of blood is as good an antiseptic covering as the genius of a Lister ever invented. And the wound treatment really belongs to our second division, to that of primary antiseptic occlusion, with this difference, that good luck has supplied the place of the surgeon's art. If his answer be in the negative, *i. e.*, he decides that the wound underneath the blood-crust is not clean, the superlative of which, in surgical language, is *not "cleanest,"* but aseptic, then it is his duty to himself and his patient to remove the blood-crust and proceed to treat the wound as belonging to those which demand primary antiseptic drainage.

In forming his decision he should bear in mind that the testimony of the latest and best observers incontestably proves that the most successful treatment is the one *which interferes the least with the wound.* A great number of cases, then, both in military and railroad service, do, or ought to, belong to the first and second divisions—those treated, *i. e.*, occluded by nature or the surgeon's art, and this number must of necessity increase in the ratio of non-interference with the wound by any one except the surgeon. Railroads should instruct their employees, and military surgeons their stewards and nurses and their wounded, under no conditions to probe the wounds with anything, but to occlude the same by means presently to be mentioned; and the surgeon himself should remember that incomparably the best results are obtained if his good judgment directs him to employ primary antiseptic occlusion.

Now, if such a case presents itself, and they are often of the gravest kind—such as compound fracture of the leg, gunshot wounds into the knee-joint, and particularly deep and extensive wounds of the thigh—the surgeon should clean all those parts which are superficial, thoroughly, with *a mixture of six parts of table salt and one part of bicarbonate of soda to* 1,000 *parts of water at the temperature of* 105–110° Fah. This wash, the same as that recommended by Mykulicz for transfusion purposes, is the least harmful to the tissues with which it comes in contact, has superior cleansing qualities, a warmth equal to that of the wounded tissues, and is antiseptic to a certain extent; yet the intent of the surgeon will most likely be frustrated if he does not observe the law of gravitation, *i. e., place his wound during the cleansing process in such a position that the fluids employed shall not gravitate into the wound, and carry with them the very elements which he seeks to exclude.*

Who is the surgeon that does not remember having been guilty of this apparently trivial omission? Who, when his presumed care in applying an antiseptic dressing was followed by the most disastrous failure, did not doubt the measure itself? His was not an aseptic wound, occluded by antiseptic means; it was a wound infected to its whole extent by the very means employed to prevent such occurrence, and then, to stay the disinfecting power resident in clean water and air, the wound was sealed up—sealed up to its fate. The open treatment in such a case would have been a thousand times more preferable. The wound opening, therefore, should be in the most dependent position when the cleansing is executed, and when completed a pledget of absorbent cotton wrung out of a $\frac{1}{1000}$ parts solution of iodo-hydrargyrate of sodium in water of 105–110° Farenheit, should be laid upon the wound for a few minutes, whilst the surgeon prepares his occlusive dressing.

The iodo-hydrargyrate of sodium solution I make as follows: Iodide of mercury, iodide of sodium, each one drachm; hot water, eight ounces. An ounce of this mixture added to a pint of hot water will make a $\frac{1}{1000}$ solution. When ready for it, the pledget of cotton is removed from the wound by the surgeon, and iodoform is evenly, and to the extent of a sixteenth of an inch (more or less according to the size of the wound), covered over the moist surface; this is followed by a thick and more extended layer of oxide of zinc. The former, in spite of its disagreeable odor, still holds, and deservedly so, the first place as an antiseptic covering, because of its efficacy and permanency; the latter, an antiseptic of no mean power, is cleanly and safe, and very much cheaper than iodoform or bismuth alone, and less dangerous than either of them. The sixteenth of an inch of iodoform would be inadequate; more of it might prove dangerous to the system, the cost not being considered, which is quite an item; whilst the extra covering with the oxide of zinc obviates all these difficulties. The powders should be covered with a small cushion prepared as follows (modified plan of Dr. George R. Fowler):

Manilla tissue paper, known as toilet paper, is cut into fine strips, about a six-

teenth of an inch in width; this is soaked in $\frac{1}{1000}$ solution of iodo-hydrargyrate of sodium already mentioned. After becoming thoroughly saturated in the solution, it is passed through the rubber rollers of a common clothes-wringer, previously washed with the same solution, then the paper is shaken out loosely, and rapidly dried. White mosquito netting, which has been treated likewise, is used for the covering of the paper cushion. Over the smaller a larger cushion is placed, and both are held in position by a gauze bandage. In cases of compound fractures, as well as in all wounds which need support in order to procure absolute rest to the parts, the common wire screening deservedly occupies the first rank in our armamentarium. It is pliable enough for any application, and can be stiffened by pleats, when they are needed. The paper dressing, though not as absorbent as other material, has the advantage of superior permeability, and when rightly applied the secretions dry more rapidly in it. This highly important desideratum is enhanced by the open wire support, and not counteracted, as is so frequently done by other devices.

Says Dr. George R. Fowler, in recommending his antiseptic paper dressing: "That perfect desiccation is the best safeguard against putrefaction is quite well known, and advantage is taken of it on our western prairies by hunters, who preserve buffalo meat by the process known as 'jerking,' *i. e.*, drying rapidly in the open air. In the first efforts made to imitate nature's process of healing under the scab, attempts were made to produce the same effect by hermetically sealing wounds by collodion and cotton, as well as by other adhesive substances. The method, however, was found to be far from successful, inasmuch as no provision was made for the draining away of the wound secretions. In the employment of the exsiccation method it is desirable to make use of a dressing through which the atmospheric air can readily pass, and which at the same time shall possess absorbent properties sufficient to permit of the removal of the wound secretions from the surface. It should likewise be capable of being impregnated with corrosive sublimate or iodo-hydrargyrate of sodium solution, the latter becoming, in the method of dressing under consideration, the preferable antiseptic agent. It will be at once seen that volatile substances, such as carbolic acid, soon become practically useless, unless confined to some extent to the wound and its surroundings by an impermeable covering. This latter would defeat the object in view, namely, rapid desiccation of the discharge."

In the application of the dressing it should be remembered that the cushions reach far over the outer edge of the powder, covering the wound, since fluids, if such are formed, penetrate between the skin and powder crust, at the margins of which they should come in contact with the absorbent dressing. Advantage of this peculiar course of the secretions may be taken in the dressing of delicate textures—by covering the wound itself with the iodoform and zinc, a little beyond the margin; then place a ring-shaped thin cushion over the parts, the inner margin of which shall just overlap the powders, and over this place the larger cushion. This method prevents any pressure upon the wound, while surface drainage and antiseptic occlusion are perfect, and desiccation greatly facilitated.

The manner of execution and the means of attaining the object—antiseptic occlusion of aseptic wounds—may be perfected; but this treatment of wounds must always remain the one which will be followed by the best results, and the percentage of recoveries will increase in the ratio of the surgeon's capacity to distinguish septic from aseptic wounds. To treat the latter in this manner must of necessity be the worst of surgery, and is to be deplored when it is done as an error of judgment, and severely condemned when it is the outgrowth of carelessness or ignorance. Now in case a wound is visibly contaminated, or a strong presumption to that effect exists, then it becomes necessary to employ primary antiseptic drainage; this is the class of cases which fall more often to the lot of the railroad surgeon.

In the first place a thorough cleaning of the wound is imperatively demanded, provided no large blood-vessel needs our immediate attention. The best material for this is the fluid already described; it is suggested because it performs the ablution of the surface very thoroughly, and a large amount may be safely employed without the risk of poisoning. I have washed out the abdominal cavity with this fluid, using gallons of it for the purpose, when all bleeding has been stopped by tying the blood-vessels carefully with the *finest* of silk threads compatible with the size of the vessel, the ligature being taken from a 1–1000 solution of the sodium iodo-hydrargyrate when needed. Torsion of vessels may stop hemorrhage and it may or may not recur; but silk ligature in the condition described seldom fails of permanent work. Cut short it

may be left in the wound, and is not likely to do mischief; such is the reported action of catgut ligature, but this may disintegrate before the condition of the blood-vessel makes it safe, and if hardened in chromic acid it may last as long as the silk thread—besides these ligatures are dearer and less easily handled than thread. For very fine work horsehair, also disinfected, becomes an acceptable ligature. Should oozing continue, then the temperature of the fluid can be raised to 120–130°, and applied to the surface with pledgets of cotton or the sponge. I prefer the former. These should never be rubbed over the wound, but gently pressed against it; if this fails, the favorite fluid of Mr. Bryant, iodine tincture and water, enough of the former to give the fluid a light brown color, may be used; this is more hæmostatic, and has proven itself an excellent agent in my hands, both for cleansing purposes and the object last named. Hæmostatics which adhere to the surface of the wound, such as sol. of persulphate of iron, belong in the category of very crude agents, and should be eschewed by the surgeon who aims at nicety and success. When all hemorrhage has stopped (and there should be no mistake about it), then the wound should be disinfected, should be made aseptic, and this can be done by filling it with the 1–4000, or if not too large, 1–1000 sol. of sodium iodohydrargyrate (the mercuric iodide only being taken in consideration in making the percentage). Certainty should exist, as near as attainable that this fluid has reached every nook of the wound. Then the wound should be gently dried, and one of three methods of suturing proceeded with. The first method is intended to be used in superficial incised wounds, and upon parts of the body where it may be possible of adjustment, and is applied according to Dr. A. B. Frazer as follows: "I take two pieces of strong adhesive plaster, as long as the cut to be drawn together, and as wide as circumstances will allow, and after folding back the edges (one-fourth inch) that are to be next the cut, I fasten ordinary dress-hooks, which are sold at the dry goods store, along the folded edges at regular intervals. Then after drying the skin, I apply the plasters on each side of the wound, a little distance from the edges, with the hooks opposite one another, and with a strong thread lace up the wound like a glove." The advantages of this method of wound suture over the ordinary kind are the following:

1. Threads can be loosened or tightened to allow for swelling.

2. The wound is accessible, and can be cleaned if this is ever necessary.

3. If sutures have to be added, the strain will be greatly lessened.

4. The plaster will hold much longer than sutures.

The second method of suturing is the one employed in perineal ruptures where the deep sutures pass under and around the wounded surfaces, and the superficial ones are used to close the integuments. This latter procedure should always be done with great care, as the fate of wound may depend upon the careful coaptation of the edges of the same. The third method and the one of general application called by its author, Mr. C. B. Keetley, "buried sutures," consists of the union of the several divided parts, each one for itself, *i. e.*, nerve end to nerve end, and muscle to muscle tissue. Whatever tissues may have been divided should be restored to their original relationships, and kept there by aseptic animal sutures; then the wound in the deep fascia must be separately sewed up, and finally the wound in the skin must be closed with catgut, or silver, or whatever is preferred. The results to be expected from this method of procedure are these:

1. There is no need of drainage tubes.

2. The sutured muscles and aponeuroses are eventually restored as regards function.

3. Deep, rough, and depressed cicatrices are avoided.

4. Necrosis of the bone and sloughing of soft tissue are prevented.

It should be remembered that sutures are employed for the most perfect coäptation of every part which has been severed by the infliction of the wound; and that such contiguity is never possible if shreds of tissue, which are likely not to retain their vitality, remain adherent upon the surfaces to be approximated. They should be removed as foreign bodies of the very worst character. A want of judgment as to the amount of tissue to be removed is grievous when too much is cut away, but decidedly disastrous when the error is in the opposite direction.

The wound, as already stated, when buried sutures are employed, is likely not to need drainage at all; but if very deep and very extensive, drainage may become necessary, and this will become urgent when the surfaces do not admit of approximation and cavities result in consequence. From John Hennen's woolen thread to Chassaignac's rubber tubes, Neuber's bone tubes, and MacEwen's horse-hair and chicken tibeæ and femora, the same principle was aimed at—the removal of fluids from the wounds—

though the earlier surgeons used them for removal of fluids pent up, particularly pus; modern surgeons, for the purpose of removing them as soon as they are formed, and for the prevention of suppuration. These tubes should be as short and as small in calibre as the demand upon them may justify, and they should not be left in the wound any longer than is necessary. Two or three days will generally suffice for this retention. Two short tubes are better than one long one and a bent tube is bad furniture. Drainage by tubes should always be facilitated by gravitation, and this is made possible very often by the direction the wound is made to take in an operation, and by the position of the patient. In fact, gravitation, assisted by position and pressure, is often the only means needed for drainage.

"It is not merely the wound itself that is benefited by preventing the accumulation of discharges, their permeation into healthy tissues, decomposition, and consequent irritation, but the nutrition of the whole limb is benefited, stasis prevented, and pathological change, once initiated, often arrested." The dry dressing of wounds is only the legitimate continuation of perfect drainage; "as a rule, the drier wounds are kept, the more quickly do they heal, and proportionately less is the suppuration. Moistening and putrefaction, drying and preservation, go together; the antiseptic power of dryness is proverbial." —Sampson Gamgee.

A dressing, therefore, which combines quick and ready absorption of fluids with rapid drying of them in its interstices; a dressing which will permit air to permeate it readily, filtering it to certain purity before it reaches the surface of the wound, a dressing which is light, non-irritating, and cheap, *is the dressing par excellence;* and such is the one already described—the paper dressing of Dr. Fowler, as modified by myself in its preparation and ultimate fixture by the wire screen.

This then, gentlemen, comprises my treatment of wounds by primary antiseptic drainage. It also comprises all there is of antiseptic practice; at least it satisfies the demands of my cases fully. In conclusion, permit me to add a few words in regard to Listerism or asepticism.

While antisepticism assumes the existence of septic matter in the wound, carried there by the injury itself, or by meddlesome and careless interference of patient, friends or surgeons, asepticism assumes the omnipresence of septic material, and seeks by its practices to exclude it from wounds. Both practices imperceptibly merge one into the other; from antiseptic drainage by the way of antiseptic occlusion, and aseptic occlusion to aseptic drainage. The first removes septic matter, the latter prevents its habitation. Aseptic occlusion is nature's most happy method, antiseptic occlusion endeavors to imitate the latter, and often very successfully; whilst the culmination of the surgeon's art of wound treatment is reached by aseptic drainage. My idea of asepticism or Listerism is perhaps, best illustrated by a description of the method adopted in my last two ovariotomies, March 16th and April 23, 1886, respectively.

My operating room, after the stove has been filled with fuel ready for lighting, is thoroughly washed (ceiling, walls, floor, doors, windows, stove, operating-table, chairs and bedstead), with carbolic acid, glycerine and water, on the evening before the operation. An hour before the operation the fire is kindled in the stove, and the temperature is raised from 115 to 120 degrees. When the temperature has fallen to 100 or 95 degrees, the hot vapor, which had been formed, will be precipitated, and anything which could have existed in the atmosphere of the room is thereby removed, making thus the very air aseptic, as near as this can be done. Now the hot and cold water are brought in, the latter having been boiled the evening before, and kept covered until ready for use. To a given quantity of this water, at a temperature ranging between 105 to 110 degrees Fah., is added a hot and filtered solution of chloride and bicarbonate of sodium in a previously ascertained quantity; so that the fluid presented to the person who alone handles the basins is of the composition already given, viz., 6 parts of the chloride and 1 part of the bicarbonate to a thousand of the water. The instruments are kept in a $\frac{1}{20}$ per cent. solution of carbolic acid in porcelain trays; the sutures and ligatures in the iodo-hydrargyrate of sodium solution in another tray, except the needles, which are dipped into the mixture when needed for use. The hands of those concerned in the work, directly or indirectly connected with the wound in the abdomen, are washed with nail-brush, soap and water, and finally in carbolic acid solution. Hands which handle the wound, and particularly the contents of the abdomen, are bathed each time this is done, in the mercurial solution. The beard and hair are moistened with bay rum containing the mercurial solution, and the hand spray moistens the clothing with the same mixture. (In my next operation

I intend to have disinfected linen dusters worn.) The coat is prohibited in the operating room, and the arms of the operator and assistant are bared to the elbow. The patients abdomen is washed with the mercurial solution, and the abdomen opened in the usual way.

When the tumor is ready for removal I adjust Thomas' clamp, then cut away the tumor, and after I have cleaned the severed surface carefully, I tie, below the clamp, with braided silk, of course strictly aseptic; then I remove the clamp and the stump is trimmed off smoothly to the distal end of the compression made by the clamp, the surface is made aseptic, and after I am fully satisfied that no oozing will take place from it, the silk is cut short and the pedicle returned into the abdomen. If no fluids have entered the abdomen, and no adhesions complicate the operation, an aseptic quilt of cotton, covered with musquito netting, is placed beneath the abdominal wound, which is not made in the linea alba, but through the rectus muscle on the left of it, to prevent abdominal hernia; the line of incision being from the linea alba at its lower edge to an inch to the left of the umbilicus. The sutures, silk also, are deep and superficial ones. They are of the second variety already mentioned, the deepest part of the curve of the deep ones just includes the edges of the peritoneum, the superficial ones the skin only.

When the oozing from the sutures has ceased, hastened by the application of the mercuric solution somewhat hotter than used hitherto, and the quilt removed, the sutures are tied and the wound is dressed, as already described for antiseptic occlusion. If the fluids have entered the abdomen, or oozing takes place from adhesions, then, after the pedicle has been returned into the abdomen, the salt water is turned into this cavity from a fountain by way of a soft rubber tube, fountain and tube surgically clean, of course; the patient being placed on her side, sufficient fluid is used to return it from the abdomen colorless, when the washing is completed with the $\frac{1}{4000}$ mercuric solution. Care is taken that the cavity is well drained, and it is now closed in the same manner already given. The former method was employed in my case of March 16, the second in my last of April 23. The first left my house on the twentieth day after the operation, the second on the twenty-second day, both perfectly recovered. In these operations I was assisted by Drs. Havemeier, Haldeman, Norris, and Huff. One of the operations was performed with the exclusive help of physicians who were my individual students once; please excuse the just pride, but it was the happiest moment in my career as a surgeon. The patient is always left in the operating room, until all dangers from infection and disturbance are passed.

Such is Listerism, as practiced by myself. You miss the spray, the several dressings, and the rubber covering; they are useless generally, and some of them, as the spray, injurious, particularly in abdominal surgery.

In conclusion, I will say that pain should not be a part of the clinical history of a case, *for pain may kill*, and, with Dr. Simon Baruch, I must say: "It is a singular fact that the chief advantage of antiseptic dressings has so often been lost sight of in discussions of this subject. To my mind, at least, it appears very probable that in the fact that by means of the antiseptic treatment of the wound and by the subsequent antiseptic absorbent dressings we are enabled to place the wound at complete rest until healing is accomplished—in this fact lies the secret of much of the success of modern surgery. Without rest repair certainly cannot proceed satisfactorily. How was it possible to give the most important element free play when the wounds were daily manipulated by undressing, sponging, syringing, and bandaging?" Whatever else Listerism may have accomplished, the greatest boon, *rest*, it has conferred upon the wounded. And shall the saving of time, trouble, and anxiety to the surgeon count for nothing?

MALARIAL HÆMATURIA.

BY CHARLES C. THORNTON, M. D.,

Of Thornton, Holmes County, Miss.

I regard this disease as a congestion. We have congestion of the brain, of the stomach, of the bowels, of the lungs, and why not of the kidneys?

Almost all the cases that I have seen have either had intermittent fever for some time, and are taken with a severe chill, or are taken from the commencement with a severe chill, and in almost every case, before hemorrhage from the kidneys supervenes, the urine is charged with bile. This is apparent when the urine is made to flow in a thin surface over the bottom of a clean white chamber, porcelain or iron-stone vase. The greenish cast, apparent to the observer, shows a redundancy of bile. Besides this physical change in the condition of the urine, the skin takes on the yellow cast so common in such cases, which only disappears when

the bowels act freely; and black, tarry bile passes freely from them, and the skin begins then to clear up, and a return to health is generally the result.

It is this acrid bile passing through the ureters and body of the kidney, the result of a congestion of the liver, or interference with the portal circulation, and the effort of nature to pass this effete matter through the urinary tract, that causes the congestion and hemorrhage from the kidney.

Twenty-six years here in a miasmatic region (the heart of the Yazoo Valley), convinces me that my theory has at least the shadow of truth or right, and then when we put the crucial test upon it, the result of my treatment, I think it is proof positive, without entering into any of the details of the symptoms. It is generally those that have had intermittent fevers for some time and neglected these, that have or are most liable to have malarial hæmaturia, and among the first symptoms are the incessant vomiting of bilious matter and the sudden discoloration of the skin, frequently in six hours after the onset of the attack, and the intense yellow, muddy appearance of the eyes, while the urine is loaded with bile, and hemorrhage soon appears, sometimes almost entirely blood, and in large quantity. As soon as I can get the bowels discharging freely *black* bile, I feel I have reached the point to hope for a favorable termination.

Now to the main point, the treatment. With a view to get up such an action on the liver and bowels to divert the bile from this unnatural to its proper channel, I give 5 to 10 grains of calomel with 1 grain each of pulverized camphor and ipecac. every 3 to 4 hours; I give lime water and fresh milk freely, or lime water alone, to correct or check the constant sick stomach; and when I can get the stomach sufficiently quiet, I give chlorate of potash and fld. ext. ergot freely; that is, to a goblet of water I add a tablespoonful chlorate potash, and a tablespoonful fld. ext. ergot, of this I give generally a tablespoonful every 2 hours; I give quinine in 3 to 5 gr. doses every 2 hours generally throughout the disease. You ask how can I give it, when the stomach is constantly irritable and there is vomiting; if I can not get it to stick by the mouth, I use No. 1 rectal capsules, or even the ordinary No. 1 gelatine capsule by the rectum. I generally give 3 or 4 of the calomel powders, and wait 12 to 24 hours, and again resort to it if necessary. There is generally little or no absorption by the stomach, and that is why so much quinine and other medicines are taken, and so little effect. The bowels at first are usually obstinately constipated; if this is not corrected generally at once, supression of urine is apt to ensue, and death as a consequence.

Is my treatment rational, empirical, or otherwise? I have the satisfaction of knowing as yet, after twenty-six years experience, I have lost no patients of this disease. My friends may say, Oh, he has never seen the disease, or not in such forms as we see it. Yes, I have seen it in all its phases. When there is a tendency to suppression of urine, I add bicarb. potash to my chlorate and ergot solution. Last year I had three cases in one house on my own place; they passed chambers almost full of blood, and six times during the day, and sometimes oftener; but to use a common term, as soon as the block is "knocked out," they are generally all right. The three cases above are now living monuments of the above practice.

I give these cases my undivided attention. I never want but one of such cases at a time.

Again to the first point, or probable cause. The first case last year was a little girl, taken with chills, had them some times every day, or every other day, when hæmaturia set in. She had two well marked exacerbations, as I term them, sinking spells, each day; generally at 12 o'clock in the day, and 12 o'clock at night, she would get cold, and the heart fag; then I would resort to brandy and milk, keeping up quinine by rectum every two hours; her temperature in axilla 102° to 105°, with quinine, would reduce to 98° each day; but at each paroxysmal time would again rise to 105°, and without quinine, would continue 103° to 105°. After bowels acting freely, black tarry actions, and water perfectly clear, the regular intermittent paroxysms would set in, and controlled by quinine, returned each seventh day for several weeks, and had to continue quinine three times a day all the summer and fall. Another, her brother, had chills; was exposed to a cold rain, had a terrible chill, and hæmaturia set in; same treatment, same success, and same results, and same tendency when well. His father, exposed to same cold rain, and worry, nursing, and anxiety about his boy, had a hard chill, and the consequences alike, I paid little attention to the bowels, even when running off almost incessantly, while these black tarry actions were passing, as the skin cleared after each action. I never use *opiates*, and warn my friends not to tamper with them. A fatal coma, and often suppression of urine, are too frequently the result of the useless administration of a single dose of opium, as I have seen, under

the impression that it would relieve some of the distressing symptoms. Calomel and quinine are my sheet anchors in this disease, while ergot and chlorate of potash assist to keep up the action of the liver, and lessen the irritation of the stomach, and control measurably the hemorrhage; but I find, as the bile is diverted to its natural channel, the hemorrhage slackens and disappears. I give quinine as an anti-ferment, for its anti-zymotic influence, and to keep the temperature within bounds. I trust only to the clinical thermometer, and register temperature every two or three hours, and watch the rise and fall, and combat these as other symptoms, the fall with brandy and milk, the rise with quinine. I give quinine all the time in fact, and the ergot and chlorate of potash whenever it will stick, and calomel as above, or alone, every three, four, or six hours, as required.

I watch my patients, and never allow any solid food until they are out of danger. I rely on a milk diet mostly—it with lime-water is retained best—chicken and beef extracts or essences I also use in moderation, but rely mostly on milk and gum arabic, with ice to allay the terrible irritability of the stomach and incessant vomiting.

THE EARLY DIAGNOSIS OF UTERINE CANCER.*

BY C. D. PALMER, M. D.,

Professor of Gynecology, Medical College of Ohio.

The author said cancer is three times more frequent in the uterus than any other organ of the body. It is occurring with increasing frequency. This increase is largely apparent, the result very naturally of improved methods in diagnosis and more frequent examinations.

The benign affections which may be confounded with cancer are chronic inflammation, eversions, granular and cystic degenerations, and ectropion.

Nothing can be easier than the diagnosis of most of the benign diseases of the cervix uteri. Nothing can be plainer than the determination of the presence of advanced cancer of this part of the uterus, by far the most common site. As it is of vital importance that we recognize a malignant disease early if we would do any radical or permanent good, and as mistakes are most generally made in the earlier stages of the disease, let us manfully consider this subject.

For practical purposes we divide the subject into two parts:

1. The form of cancer simulating or confounded with parenchymatous or fibrous benign disease of the cervix.

2. The form of cancer mistaken for simulating or simulated by endometrial benign disease.

Probably the origin of cancer begins in a degeneration of the connective tissue cells, either under the mucous membrane on the vaginal face of the cervix, or up within the cervical canal, while the epithelial growths or ulcerations first invade the superficial epithelium. A carcinomatous infiltration arising within the connective tissue cells of the cervix at once heightens the vascularity of the part, which looks reddish or bluish in color. It produces nodulations more or less hard and diminishes the mobility of the subjacent mucous membrane. Should these changes start in a cervix previously healthy, or so little diseased as to excite no special attention, they progress so insidiously, it may be slowly, that in all probability the patient will not call on her physician until the second or ulcerative state has advanced. Or, should they commence in a cervix already diseased by chronic inflammation, one that is being inspected for treatment from time to time, they may even advance to a considerable degree before any special suspicion is excited. The general health may be good or bad. The author thought that in most instances a diagnosis could now be made. The one thing needful is that a suspicion of malignancy be aroused, The symptom of Spiegelberg is not as reliable as was at first supposed. Much can be learned by watching the development of treatment. It may be observed that while all the local conditions, leucorrhœa, erosion, induration, etc., do improve under a well directed local treatment, provided they are the offspring of an inflammation, yet if malignant they do not improve at all, and if so but slightly, never permanently. They manifest a special obstinacy to treatment; in fact, they progressively get worse. In women of advanced years such development should excite the gravest suspicions. If any doubts now remain, resort should be made to the microscope. I doubt if the microscopist can give us a reliable opinion without any other clinical evidences at hand; but with them the microscope becomes strongly corroborative and confirmatory. Fungoid degenerations may remain for a long time innocent formations, yet on the other hand they may quickly develop into malignancy. This

*Read before the Cincinnati Academy of Medicine, June 14, 1886. Abstract.

transformation may be exceedingly slow, consuming years. This is important to remember, so that we may not be thrown off our guard. Unquestionably malignant epitheliomatous degeneration is more likely to ensue in cases of cervical laceration in which the torn surfaces never cicatrize. Cicatrization, however, is not a barrier. The author recommended the use of the microscope and all other means of diagnosis, and thought the topical applications of glycerites of tannin, alum, and boracic acid to be of especial benefit in diagnosis.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

(*Continued from page* 79.)

Dr. Harris heard of this case a week after its commencement, and believed from what he knew of it at that time that it would be advisable to perform the laparotomy: but subsequent developments indicated that the hemorrhage was extra-peritoneal and gradual, and there was, therefore, no immediate danger to be overcome. When, however, he saw the patient, October 28, he was satisfied that her constitutional symptoms required that an exploration of the abdominal cavity should be made, the blood cyst defined, and then that the blood should be evacuated above left groin. This opinion being sustained in the consultation, the operation was performed accordingly.

Dr. Price inquired if any examination of the condition of the gall bladder and duct had been made at the time of operation. Was the jaundice due to mechanical obstruction or to the general condition?

Dr. Baer at first thought an error had been committed in not operating at first when the diagnosis was made and the tube ruptured; but the full history puts the matter in a different light, and would cause great hesitancy about rushing in on a similar case.

Dr. O'Hara had made his diagnosis at the time of the accident. Operation could not have been performed then on account of the collapse, and after that passed away it did not seemed called for until the time of its performance. One question has risen in his mind, from the subsequent history of the case. Would it not have been better if the wound had been packed from the time of the operation?

Sanger's Cæsarean Operation.

Dr. Robert P. Harris said: I desire through this Society to give publicity to the following statement, received a few days ago in a letter from Dr. Sänger, of Leipzig, by which it will be seen that his method now stands unrivaled in the world, in its ability to save human life. Locally considered, the Porro operation as performed in the Santa Caterina Hospital of Milan, Italy, has until recently far exceeded in its proportionate success all other Cæsarean methods in any hospital or country; but this, the best of all Porro successes, has now to be rated second, as compared with its younger German rival. Laparo-elytrotomy, a year ago, stood upon the same level with the Sänger operation in its rate of success; but now the latter far outstrips it in the number of times it has been performed and in its proportion of cures. According to Dr. Sänger's letter, his operation, with its modifications and simplifications, has been performed 25 times, saving 18 women, or 72 per cent., and resulting in 22 children being delivered alive, or 88 per cent. In these are included three fatal American cases, which if not in an absolutely hopeless state before the operation, gave a very minimum hope of success. The European 22 operations saved 18 women or $81\frac{9}{11}$ per cent. In the Maternity Hospital of Leipzig, Dr. Sänger has operated 4 times, Dr. Obermann once, and Dr. Donal once, saving all of the women and children; in but one woman was there any special trouble after the operation. Dr. Leopold, of the Dresden Maternity Hospital, has operated 9 times, and Dr. Korn once; the former lost one woman; all of the children were saved. Thus we have 15 women and 16 children saved under 16 operations, a mortality for the former of only $6\frac{1}{4}$ per cent. Of the four deaths in Europe two resulted from septic poisoning, which existed at the time of the operation, and in the other two subjects it followed it.

Dr. Sänger has such confidence in his method from the success that has attended it in Germany that he believes the time has come when it should be preferred to craniotomy, because of its moderate fatality, and its saving the child. We should be glad if all of the Cæsarean operations of the United States should be performed after Sänger's method as simplified by Garrigues and Leopold, but we must not accept very happy results here until our accoucheurs become alive to the fact that delay in operating will make any method fatal in a large proportion of cases. In no country are the capabilities of the old Cæsarean operation greater than in the United States, and in few has

this form of delivery been of late more uniformly fatal. To find 18 recoveries under it, we must search backward to January, 1863, and through a record of time covering more than 23 years, in which period 73 operations have been performed, proving fatal in about 75 per cent. This occurred notwithstanding an established fact that a set of early operations will save 75 per cent. of the women and still higher of the children in the United States.

Tait on Faradization.

Dr. R. P. Harris, also presented the following letter from Mr. Lawson Tait, of Birmingham, dated April 16, 1886; "I have very strong objections to the proposal to treat cases of extra-uterine pregnancy by faradization. In the first place the diagnosis of these cases must always be hap-hazard; that is to say, a correct diagnosis will not be made probably more than once in three times; the result will be that all such cases will be dealt with mischievously only, and I venture to predict that this treatment will be dropped, as all such treatments are, without explanation of the case, in a very short time. My greatest objection is that, supposing the fœtus has passed through the stage of tubal rupture and remained alive, what right have you to murder that child? If it goes on to the full time it may be delivered alive, and the woman will have a chance of recovery from the operation far greater than with the faradization treatment of destroying the child. The cases, according to my experience, which recover from the operation, are about six out of seven."

"Every one who has had much experience with pelvic tumors must have seen a certain number of cases where the fœtus has died between the fourth and sixth month, and where, after a prolonged course of suppuration, it comes out through the rectum, bladder, etc.; there are, of course, the cases where the tubal rupture has taken place into the broad ligament on the left side. I have seen one right-sided case going into the bladder; it, of course, killed the patient."

"In the whole course of my life I have only known of one case where the woman has carried an extra-uterine pregnancy for a number of years after the death of the fœtus. We knew with perfect certainty all about this case, and for about eighteen years she has carried on the left side a condensed ovum of extra-uterine pregnancy. I doubt very much if there could be found in the whole world three other such cases; whereas the number of cases who die, or who have prolonged illness after the suppuration and discharge of the fœtus is, even in my own experience, very great."

In closing his letter, Mr. Tait writes: "I wish you would make this opinion of mine known on your side."

In reply, I will state:

1. We do not, in this country, practice electrolysis in cases of extra-uterine pregnancy. No puncturing needles are used, and the electro-magnetic current will not endanger the life of the patient any more if the growth to be acted upon is a tumor than if it be, as presumed, an ectopic fœtal cyst. The experience of seventeen years in the United States, in which no fatal result is believed to have taken place, has only tended to establish this fœticidal method as a valuable means of saving women when in great danger of death from rupture of the fœtal cyst and internal hemorrhage.

2. We do not propose to act upon the fœtus after it has escaped into the abdominal cavity, unless the fœtus should be very small, and be easily accessible to the pole of the battery placed in the vagina. We cannot see that it is any more a murder to destroy a two or three months' fœtus after it has escaped from a Fallopian tube by rupture than while it is still in it. The chief objection lies in the fact that such an ectopic fœtus will be much more likely to give trouble after its destruction than one that is securely enclosed in a sac from which the amniotic fluid shall have been absorbed. It is true that an abdominal fœtus may be delivered alive at term, if permitted to live; but it is not correct to estimate the risk of such an operation as lower than faradization properly performed, for it is far higher. Primary laparotomy, as far as we know of the operations, has been fatal in fifteen out of nineteen cases.

It is not proposed in this country to operate by faradization upon fœtuses of from four to six months. Dr. T. G. Thomas has, it is true, proposed to make the limit four and a half months, but the general impression is that fœticide is much safer, immediately and remotely, if done in the second and third months, when fœtal ossification is very incomplete. The entrance of fœtal debris into the bladder is not necessarily fatal, as in the case related by Mr. Tait, for Parry refers to nine cases, four of which recovered.

Mr. Tait appears not to be aware of the fact that cases of prolonged ectopic gestation have been comparatively numerous, as witness the following partial record:

1. Nebel reports the case of a woman of

91. who died in 1767, and in whose body a fœtus was found that she had carried 55 years (Campbell on Extra-uterine Pregnancy, 1840, page 45).

2. Brandt records one of a woman of 80, who died in 1858, after carrying a fœtus for 56 years, and bore two children while it was still in her abdomen (Ranking's Abstract, 1863, vol. i., page 216).

3. Parkhurst reports one of a woman of 77, who carried a fœtus 52 years (British and Foreign Med. Chi. Rev., 1856, vol. i., page 271).

4. Chiari gives a case of a patient who died of pneumonia when 82, who carried an 8 months' fœtus for 50 years (*Lancet*, Lond., 1876, vol. ii., page 141).

5. Conant's case was a woman of 63, who died in June, 1863, after carrying a fœtus 35 years (*New York Med. Jour.*, May, 1865).

6. Majon found in a woman of 78 a calcareous fœtus, computed at three months (Cruveilhier, Essai sur l'Anatomie Pathologique, Paris, 1816, tome ii., page 130).

7. Mangin Vernier found two fœtuses in the body of a woman of 74. which she had carried 33 years (*Jour. de Medecine*, 1786; *Gaz. Med.*, July 29, 1837).

8. Morand also found a 3 months' fœtus in a woman of 78; she had carried it 30 years (Mem. de l'Acad. Roy. des Sciences, 1748).

9. Christian Grön found a 3 months' fœtus in a woman of 49, which had been carried 18 years (*Norsk Magazin for Lœgevidensk*, band xvii., haft 2).

10. Johannes Ambosi (1552) reported a case of a woman of Sens, who carried a fœtus 28 years (see *Astruc. Traite des Mal. des Femmes*, Paris, 1765, tome iv., p. 78).

11. Campbell reports the case of a woman of 75, in whom was found a fœtus that had been carried 30 years; a fœtus of about two months was also found (C. on Extra-uterine Gestation, Edin., 1840, p. 55).

12. Pepper relates the case of a patient of 53, married 27 years, in whose body Dr. Loder found two fœtuses, one carried 23 years (Trans. Pathol. Soc., Phila., 1876, p. 102).

13. Francis Boyle removed an 8 pound fœtus after the death of a woman of Toulouse, that she had carried 26 years (Philos. Trans. Abrid., London, 1794, vol. iii., p. 222).

14. Cruveilhier, in his *Anatomie Pathologique*, gives a plate representing a calcified fœtus which had been carried many years.

15. Œlinger reports a case of a woman who carried a six and a half months' fœtus about fifteen years (*Prog. Med.*, Paris, 1884, vol. xii., p. 196).

16. Johnson's case, aged 68, carried a fœtus fourteen years, after which she discharged fœtal remains at intervals during thirty years (*Med. Times*, London, 1872, vol. i., p. 655).

17. Leinzell, in 1720, removed from the body of a woman of ninety-four, a fœtus that she had carried for forty-six years.

18. Watkins examined a woman of seventy-four who died of kidney disease, January 13, 1864, and removed a fœtus which she had carried for forty-three years (*Brit. Med. Jour.*, March 3, 1866).

19. Van Swieten also records the case of a woman of Lyons who died at sixty-eight and had carried a fœtus for twenty-seven years (*opus cit.*).

20. Fabri, of Ravenna, found in a woman of fifty-five a fœtus she had carried for some years. The pregnancy was her fifth, and she bore two children at later periods (*Brit. Med. Jour.*, March 7, 1863).

Many more cases of the same character might be added to this list, some of which would go to show that an extra-uterine fœtus may prove fatal by purulent disintegration and pointing after twenty years or more. Even an ectopic fœtus of three months may cause perforation of the rectum and possibly a fatal issue, although this is a rare result; it will be noticed that in three of the twenty-one cases the fœtus was computed at three months, and in another, a second fœtus was of two months.

Dr. O'Hara exhibited a

Fibro-Cystic Tumor of the Uterus

removed after death from a patient aged fifty-three years, who had carried it for over twenty years. Three years after it was first observed she applied to Dr. Atlee for relief by operation; but he declined, and recommended that it should be let alone. The tumor contained numerous small cysts and measured thirty-nine and one-half by thirty-four inches in circumferences, and weighed thirty pounds. The peritoneum was one-fourth inch in thickness and was of a yellowish-white color.

Dr. Parish remarked that the tumor had formed no adhesions with the exception of a few slight ones to the omentum, and the removal of the ovaries and tubes would have been feasible at any time. Both tubes were dilated and in a condition of hydro-salpinx. The tumor sprung from the fundus uteri, the cavity measuring only four inches. The tubes and ovaries had remained at their nor-

mal position in relation to the uterus, but had been elevated out of the true pelvis. The vagina had been stretched upwards, as also had been the uterine body and neck. The uterus below the fundus had diminished in size to about that of the index finger. The bladder, by reason of the traction upward, had lost its attachments to the uterus and merely retained posteriorly its attachment to the vagina. Ordinarily the extent of the attachment of the bladder to the uterus becomes greatly increased in large uterine fibroids. In the specimen submitted, supra-vaginal amputation of the uterus with the tumor could have been effected without separation of the bladder from any of its attachments. It is interesting to observe the condition of bilateral hydro-salpinx some six years after the menopause. The patient died with acute symptoms of vomiting and purging of dark fluids, containing probably blood extravasated through the intestinal walls. At the autopsy, no indications of perforation of the intestine were apparent. The patient was able to engage in active work until a few days prior to death, and hence the double hydro-salpinx could not have occasioned pronounced symptoms.

On the Statistics of 3036 Cases of Labor, by Hiram Corson, M. D.

Dr. Wm. Goodell read the paper, which will be published in full in the *New York Medical Journal.*

In the Transactions of the Medical Society of the State of Pennsylvania for 1863 may be found an article headed "Midwifery in the Country," in which are drawn statistics from 2387 consecutive cases of labor, to which are now added 649 cases, making in all 3036 cases, with 3087 children. Head presentations (vertex), 3012; breech, including knees and feet, 58; shoulder and arm, 5; face, 12. Twins in 51 cases. Ergot was used in 139 cases in first series. Forceps were used 28 times in the first 2387 cases, and 31 times in the last 649 cases. Version was performed twice in the last series. One primipara was 52 years of age. Puerperal convulsions in eight cases, all recovered. There was a total of 190 cases, in which the children were born before the doctor arrived, and in which the mothers did well under nature's management, and were saved the fright and suffering which, if Credé had been present, would have resulted from his fears of hemorrhage, his rush of one hand into the vagina the moment after the child was born, and the grasping, squeezing, and forcing down of the womb by the other hand on the tender, sore abdomen, to say nothing of having that heavy hand pressing on a tight bandage for two hours more, in accordance with regulation orders.

In the practice of this art I have not followed the requirements of the times. I have considered labor a natural process, and that my duty consisted in awaiting the action of the patient's forces; not setting them aside and myself usurping the duties which the natural efforts would have achieved without difficulty, but coming to my patient's aid only when her forces seemed inadequate to the performance of their duties.

I have learned that the forceps are used very often, many, many times oftener in proportion to number of cases than twenty years ago, and that this is done in the early part of the labor, not because nature is inadequate to the work, but because as the physician had never hurt *himself* by using the instrument, and wished to get away speedily, as he had other patients who needed attention; and though the condition of the lying-in woman would well have permitted him to visit his other patients and return in time to aid her if she needed aid, still he would not do it, through fear that the child might be born in his absence, or some other doctor be called in his place. The graduate of a month can now use the forceps and all the other swift-sure means of speedy delivery without hurting his hands or spraining his back. Of course the sufferings and fate of the woman were of secondary importance. Being anxious to learn all about the advances in midwifery, I attended the meeting of the American Gynecological Association in Philadelphia, a few years ago. There I heard from the mouth of more than one eminent gynecologist—men greater than midwives: "Every year I use the forceps more frequently than before." There too I was amazed to learn from the experience of these speakers, how numerous were the cases of lacerations of the cervix and perineum; so numerous, indeed, that when coupled with the fact that the advocates of frequent use of the forceps were teachers of midwifery, and also eminent surgeons skillful to "repair" these lacerations, and that these repairs brought large remuneration to the surgeons, I was dazed—I knew not what to say. I could not believe it possible that the earnest gentlemen before me could have conspired to teach this rushing plan of delivery in order that lacerations should be produced, so that the business of repairing should be brisk and profitable. It was pleasant, a few months later, to hear that the eminent gynecologist, Dr. Goodell, attributed the

great increase of lacerations to the use of the forceps, and earnestly denounced their indiscriminate employment.

In October, 1880, the *Boston Medical and Surgical Journal* contained an article by J. W. Elliott, M. D., on "Antiseptics in Gynecology," with full directions for their use in obstetrics, to prevent puerperal fever by destroying poison-germs which might be introduced by the doctor or nurse. "At the beginning of labor the patient should have a hip-bath, the hair should be cut away from the genitals, the vagina and vulva should be washed with soap and disinfected with carbolic acid. During labor every examination should be preceded by a vaginal injection of a three per cent. carbolic solution, to prevent the examining finger carrying germs lodged at the vulva or in the vagina up to the uterus (which is about to be more or less lacerated). After delivery, the uterus and vagina should be considered as a deep and important wound, which may heal by first intention, or in which the secretions may stagnate, become putrid, and be absorbed."

As I had never before heard of Dr. Elliott, I went on in my usual way, taking no razor to shave the parts, no syringe, no carbolic acid, but let nature go on with her work, pleased to see how steadily and perfectly she accomplished it. Dr. Corson asks, Is labor a natural process? Are antiseptic solutions when thrown into the uterus and vagina safe? and answers these questions from the standpoint of his own experience, and by quotations from Albert H. Smith's lecture "On the Relation of Cleanliness to the Prevention of Puerperal Septicæmia;" Dr. W. O. Stillman's account of the precautions taken by Carl Braun, of Vienna, to prevent infection to the lying-in woman; Dr. T. G. Thomas, of New York, a paper read before the New York Academy; Dr. George J. Harrison, in reply to Dr. Thomas; and to papers by Fritsch and Kustner, and gives his own experience in his first labor case in 1827.

Dr. Corson next considers the forced delivery of the placenta, and claims the originality of the Credé method in its principal details for Professors James and Dewees, the latter saying that it had been long since recommended by Monsieur Darsé, of Paris. He criticises the unnecessary severity of the latter part of the Credé method, and much prefers the directions given by Prof. Penrose, and then details his own method, which leaves more to natural powers, giving morphia if rigid contractions of the os occur before the placenta comes away.

He recommends venesection to the extent of ten or twenty ounces, to relax a rigidly contracted os in the first stage of labor. If this is not immediately successful, he gives morphia internally. He uses ether to relax when pains are too severe.

Dr. Corson next considers the question of tying the cord. Should it be tied at all? How soon after birth should it be divided? What is gained by waiting until pulsation ceases in the cord? These are questions to which careful consideration has been given, and which are fully answered. Dr. Corson does not use a binder; has not done so for twenty (20) years. He does not think that it prevents relaxation of the uterus, but that it favors prolapse of that organ. He gives his own experience, and fortifies it by that of several other physicians. He thinks the hasty extraction of the placenta, the compression of the uterus by the hand, and the application of the binder with the avowed intention of preventing hemorrhage, have a bad mental effect on the patient, and predispose to the very trouble we are seeking to avoid. He gives several instances of mental influences in stopping hemorrhage. He has never used hot water, vinegar, lemon, or ice into the uterus for flooding, but has applied ice externally.

Puerperal convulsions, ten cases, all recovered. His treatment consists largely in free venesection, cold water poured over the head, and morphia internally. He recommends the hand-book of Dr. Ezra Michener for the successful treatment of this malady. He would also avert convulsions by bleeding before labor to relieve headaches, if accompanied by congestion of the face. Of puerperal or septicæmic fever he knows nothing, having never seen it.

W. H. H. Githens, *Secretary.*

THE CLINICAL SOCIETY OF MARYLAND.

Stated meeting held April 16, 1886.

The President, Dr. L. McLane Tiffany in the chair.

Dr. Joseph Bloom read a paper on

Periodic Rhinitis (*see page 68*),

giving his personal experience as a sufferer from the disease.

Treatment of Carbuncle.

Dr. Wm. H. Norris wished to call attention to very satisfactory results he had recently obtained in the treatment of two large carbuncles by the carbolic acid method.

They were very large, one being 4 by 6 inches, the other somewhat smaller. The acid in solution was injected into and around the carbuncle, and in two days they were converted into healthy open granulating ulcers, that rapidly healed.

Dr. Pole has had good results from the use of caustic potash in these troubles.

Dr. G. H. Rohé considers cutting, with the internal administration of quinine and iron the proper treatment for carbuncle. He protests against the use of caustic potash because of its being an unsurgical procedure, whose action cannot be controlled after it is once applied.

Dr. John Chambers questions the accuracy of the diagnosis in many of the cases of carbuncle reported as cured by the carbolic acid method.

He don't think it quite so common an affection.

Dr. Randolph Winslow sees good in both lines of treatment; but in many of those affected with carbuncle, we have patients who could hardly bear the loss of blood sometimes consequent upon the cutting treatment. He considers the carbolic acid method ordinarily a good line of treatment.

Dr. L. McLane Tiffany don't think any recent observer justified in claiming originality for the use of carbolic acid in carbuncle. He recalls a case treated after that method by him in 1867, and it was not then original with him.

It was introduced for its germicide effects, upon the ground that carbuncle was the result of the presence of a coccus in the tissues. The plan is to inject with a hypodermic syringe a 10 per cent. solution of the acid into and around the diseased area. It causes sloughing and usually converts it into a healthy granulating ulcer. It is less painful than the knife, and as good in its results.

Dr. Strauss called attention to the failure of emetics in a case of strychnia poisoning recently seen by him. The patient was supposed to have swallowed about 45 grains of strychnia. Two minutes afterwards he had opisthotonos. Apomorphia was given hypodermically without effect. A effort to pump out the stomach was made, but the spasm of the œsophageal muscles was so great that the tube was compressed, and no great fluid could be brought away. The patient died of asphyxia in half hour.

Dr. Wm. Massey reported a case of

Hysterical Aphonia,

in which the treatment recommended by Dr. Flint in his practice of medicine accomplished a cure.

The treatment referred to is, when all others fail, then resort to alcohol to intoxication. The doctor acted upon this suggestion, and on the following morning the woman was in her natural voice.

Under the head of miscellaneous business, Dr. F. A. Morawetz was appointed a delegate to the Medical and Chirurgical Faculty of Maryland.

Editorial Department.

Mollities Ossium in the Male, with Spontaneous Fractures.

Dr. James A. Rigby thus writes in the *Brit. Med. Jour.*, July 3:

The extreme rarity of mollities ossium, in the male, induces me to bring under notice the following case. Concerning the rarity of this disease, Bristowe (*Theory and Practice of Medicine*, 1876, page 901) says: "It has been recognized only in women; and, for the most part, in women who are bearing children." Niemeyer (*Text-book of Practical Medicine*, vol. ii., page 565) says: "This is a rare disease; up to the present time, it has been observed almost exclusively in women." Trousseau (*Clinical Medicine*, vol. v.), who names the disease adult rickets, does not specifically assert that it is never met with in men, yet, all the cases he mentions occurred in women; and he seems to assume that the disease is exclusively confined to women, particularly to women just after repeated pregnancies. Sir William MacCormac (Quain's *Dictionary of Medicine*, page 997) states that mollities ossium "affects the female sex almost exclusively; only occurs in adults, and during the period of child-bearing." He also says it "very rarely is observed in the male sex."

William G., aged 43, married, a schoolmaster, with no family history of any softening of the bones, about eight years ago began to suffer from severe pains in his knees, attributed to rheumatism. Then pains came in his feet and shoulders. He was also dyspeptic, and always of a costive nature. Four years ago he began to be much troubled with

pains in his hips, and difficult locomotion. These increased steadily till he was unable to walk erect; then he gave way on the right side so much, that he thought his right hip was either wholly or partially dislocated.

Coincidently with these alterations in the hips, the hands began to undergo changes, which have ultimately resulted in the present state of things. There is a more or less complete absorption of the muscular tissue of the hands; the ungual phalanges are all shortened in a marked degree; the articular extremities of the other phalanges are enlarged at the base. This is most distinctly perceptible in the thumb, of which the base of the first phalanx is so much enlarged, that it causes the extensor tendon to run in a curved direction, something like the course of the string passing over the bridge of a violin; the obvious effect of this is to cause insufficiency of length of tendon, and so dislocation backwards of the ungual phalanx of the thumb; the pad of the thumb is thus placed transversely on the end of the thumb, and looks upwards, instead of forwards, towards the palmar aspect.

The chest has altered much in shape. It is now more or less rounded in every diameter, compressed laterally, and bulging forwards, more particularly at the lower part. There are well marked swellings at the junction of the ribs with the costal cartilages. The sternum is sickle-shaped, the handle being upwards, and the convex surface of the sickle looking forwards.

Two years ago, the patient sustained a fracture of the right humerus, through simply trying to prevent a man from jostling him in the street.

On December 29th last, the patient first came under my care. He was then quite unable to walk without a crutch and stick. He had been bending down to tie his bootlace, when the right femur broke through the middle of its shaft. The fracture united distinctly in six weeks. Meantime, the patient suffered from considerable pain in the left thigh, the muscles of which wasted. While he was still in bed, the left femur bowed outwards, and seemed to rotate on its axis, so that the front aspect of the knee turned outwards. Soon after its reunion, the fractured right femur became subject to very similar alteration in shape, though a little more marked.

The bones of the head remained unaltered. The organs are quite healthy. The mental faculties are perfect. He has no cough, diarrhœa, or perspirations; no pyrexia or hectic.

Remarks.—The above is a typical case of mollities ossium. Numerous views have been advanced as to the nature of this disease. Trousseau (*Clinical Medicine*, vol. v., page 81,) says: "Ought we to consider that there is a similarity between osteo-malacia and rickets? I say we ought. In my opinion, and in that of many other physicians, they are one and the same." This opinion he supports by statements, for which I must refer readers to the article itself; but which, in my experience, are quite contrary to fact. For instance, in the case above described, there is an entire absence of the constitutional symptoms which are characteristic of rickets; pyrexia, profuse sweats, soreness of the bones, derangements of the alimentary tract, and inflammatory affections of the respiratory organs. Again, in alluding to the occurrence of fractures in rickets, he says (*Ibid.* page 81), there is a "greater rarity of fractures in the rickets of adults than in the rickets of children." This is quite contrary to my experience; for, unfortunately, in Preston, rickets is most prevalent, yet I never have seen a case of spontaneous fracture in any out of a very large number of cases I have attended. Moreover, rickets is generally traceable to some definite cause, chiefly dietetic; but, in the case described, there is a total inability to discover any predisposing cause.

Niemeyer, in discussing the etiology of osteo-malacia, says (*Op. cit.*, page 565), that, in this disease, "bones which have been hard become soft from re-absorption of the salts of lime. This explanation of the disease at once shows its difference from rachitis, where the lime-salts do not disappear from the bones, but have never been deposited there." I think it is open to some doubt, and contrary to clinical experience, to say that, in rickets, the lime-salts do not disappear from the bones. In rickets, a bone that has hitherto been rigid and unbendable, becomes soft and yielding; and, I think, it requires something more than a mere *ipse dixit* to say that, in such a case, there has been no re-absorption of calcareous matter already deposited. Niemeyer further says: "The exciting causes are unknown; we only know that the first signs of it, in most cases, appeared some time after confinement, so that pregnancy, parturition, or the puerperal state, undoubtedly have much to do with the etiology." The effect of this statement is, undoubtedly, very much weakened by the fact that, in the case described above, the patient is a male; which clearly proves one thing, at any rate, that osteo-malacia may

occur totally independent of pregnancy; so that, as fixed factors in the causation of this disease, pregnancy, parturition, and the puerperal state is non-existent.

The Treatment of Acute Sporadic Dysenteries.

Dr. Q. C. Smith thus writes in the *Southern Practitioner*, for July:

The remedies we have found most useful in the treatment of acute dysenteries, are as follows: Belladonna, ipecac, capsicum, gelsemium, aconite, iodine, nux vomica, spirits turpentine, cinchona, baptisia, aromatic spirits ammonia, salicin, lupulin, logwood, subnitrate of bismuth, and vegetable charcoal. However, no one case is likely to require the use of so many remedies as all those just enumerated; but 'tis rare that other remedies than those just mentioned are required to successfully treat even severe cases of acute dysentery. Sporadic acute dysentery is generally preceded by a diarrhœal condition of one or two or more days, and when first called to a severe case of acute dysentery, we usually find the patient in great pain, of a more or less paroxysmal character, which is greatly aggravated at each frequent alvine effort, small bloody mucus discharges, lower abdomen tender on pressure, renal secretion greatly diminished or suppressed, soft pulse, more or less fever, thirst, irritable stomach, foul tongue, and loss of appetite. Such cases are often aggravated and seriously complicated by the administration of opium previous to the physician being called, who may be so unwise as to continue the administration of this delusive, but most pernicious drug—in the treatment of dysenteries. To quickly relieve such a case as we have just briefly outlined, we would begin by immediately giving a hypodermic of $\frac{1}{60}$ to $\frac{1}{30}$ grain sulph. atropia, cover the abdomen with dry, thick, hot cloths, applying soothing liniment to the abdomen if there be great pain, frequent *small* drinks of cool, acidulated drinks, or plain water. Soon the patient will be greatly relieved of pain, and the stomach in retainable condition. Then, say an hour after the hypodermic, begin the administration of something like the following:

℞. Fl. ex. belladonna, ℥j.
Green tr. gelsemium, ℥ij.
Tr. aconite rad. (Fleming's) gtt. iv.
Arom. spirits ammonia, ℥ss.
Elix. lactopeptine, q. s. ft., ℥ij.
M. Ft. sol.
S.—Teaspoonful every one to three hours, as may be required to control pain in the bowels.

Also:

℞. Ex. cinchona,
Ex. lupulin, āā gtt. xii.
Ex. capsicum, gtt. ij.
Ex. ipecac, gtt. iv.
M. Ft. 12 pills and silver coat.
S.—One pill three times a day—preferably just after meals.

Should the renal secretion be suppressed, or notably diminished, spirits turpentine, prepared as follows, would be in order:

℞. Spirits turpentine,
Sugar milk,
Pure sugar, āā ℥j.
Oil sassafras, gtt. iv.
Chloroform water, ℥ss.
Mix well.

Add:

℞. Fl. ex. ipecac, gtt. ij.
Cinnamon water, q. s. ad f. ℥ij.
M. Ft. emulsion.
S.—Teaspoonful every two to four hours until renal secretion is restored.

Spirits turpentine is also a valuable remedy in the more advanced stages of many cases of dysentery. But should the case have gone on for several days, from bad to worse, then other remedies, in addition to those just formulated, are often beneficial.

If the alvine discharges are very fœtid, vegetable charcoal, spirits turpentine, and baptisia are in order. If there be a tendency to diarrhœa, then salicin, subnitrate of bismuth, and logwood would be appropriate. In malarial dysentery—in addition to the remedies formulated—cinchona, iodine, ipecac, and arsenic, would be specially indicated.

In all forms, and in all stages, special attention should be given toward aiding digestion, for the diet of dysenteric patients is a matter of the first importance in all cases. For with the horizontal rest, proper alimentation, and care, many cases will speedily recover without the use of drugs. But only one or two kinds of food should be given at any one meal, and food should not be taken oftener than three times a day.

The prepared infant foods, and pepsin, serve a valuable purpose in many cases. Well-cooked and seasoned green salads with vinegar, good ripe fruits, cooked or raw, such as peaches, apples, grapes, oranges, lemons, dates, and figs, farinaceous foods, soups, well broiled and seasoned fat mutton chops, and beefsteaks, good fresh sweet milk, and butter milk, with fresh butter on toasted light bread. Such are the articles of food we usually prescribe for dysenteric patients, with satisfaction to ourselves and benefit to the patient.

Opium, mercury, and starvation are respon-

sible for thousands of preventable deaths from dysentery.

Quinine in the Treatment of Whooping-Cough.

Dr. W. Thornton Parker thus writes in the *Med. Times*, June 26:

A communication which I lately read in one of our journals concerning the treatment of whooping-cough with quinine in *large* doses has suggested to me that my own experience with this treatment for the past six years may be worth recording. I am the more inclined to do this since noticing that in the *Brit. Med. Jour.*, of February 6, the question has been again raised as to what is the best treatment for cases of whooping-cough.

During the past six years I have treated upwards of one hundred cases of this disease, and the principal remedy has been sulphate of quinine in solution. With very few exceptions, this treatment has proved perfectly satisfactory. Only in cases where the hygienic surroundings have not been good, or where the remedy was not faithfully or regularly employed, or where unusually obstinate symptoms prevailed, has this excellent remedy failed to relieve, if not actually to cure. The paroxysms diminish in frequency, and the little patient shows unmistakable signs of improvement as early as the second day. With regard to Dr. Sauerhering's treatment with powders of sulphate of quinine, I have found that method less desirable, and have used it only a few times, trusting entirely to solution of sulphate of quinine varying in strength according to the age of the patient and the severity of the disease.

The employment of the solution affects at once the coughing, and the vomiting is not severe enough to occasion any considerable alarm. A certain amount of nausea, sufficient to disengage the mucous secretions, is of course desirable. Even if this treatment should be found disappointing as a *specific*, it is certainly useful in that it places the patient at once under the most favorable circumstances for a recovery, removing or relieving many of the painful and prominent sources of the disease.

Under this method of treatment complications are guarded against, and the patient's general condition is vastly superior to that of children treated with such remedies as belladonna, for instance, or other well-known depressants, and cough-syrups. The treatment with sulphate of quinine is a rational treatment. The treatment with cough-mixtures is often only a miserable attempt at palliation.

The favorable statistics of Dr. Sauerhering will be found greatly increased by Dr. Dawson's method, and a perusal of the latter's little pamphlet* on the subject will explain the *modus operandi*, so that any one can employ the treatment with a reasonable hope of success.

Dr. Dawson introduced this treatment from Germany, and first used it in the wards of the Hospital for Children in New York City, then under his care. He met with great success. In 1880, I employed this treatment in many cases in private practice. I was so much pleased with its workings, and the almost immediate relief afforded, that I have used it and recommended it ever since. The treatment which I follow is to expose the patient as much as possible to the open air, and, if practicable, at our mountain or ocean resorts, paying particular attention to food and clothing and general hygienic conditions. Every two hours I give a teaspoonful of a solution of sulphate of quinine four, six, eight, or even ten grains to the ounce. This remedy does not disappoint in many cases in controlling the disease, and, if properly used, and with perseverance, in actually curing it, or at least shortening its course very decidedly. It seems to act as a sedative on the inflamed mucous membrane, and has also the valuable properties of a tonic. Unlike many of the other remedies which are so unsuccessfully exhibited in this disease, it has absolutely no injurious effects. The little patients begin to improve very shortly after the first two or three doses. I am fully convinced that a trial should always be made of the solution of sulphate of quinine in the strength and in the doses indicated, according to the age of the patient and the severity of the case; and after a few faithful experiments in this direction, I believe that no one will be able to say with truth that "the course of the disease could not be controlled by treatment."

Prurigo.

Dr. James A. Myrtle thus writes to the *Brit. Med. Jour.*, June 26:

A very typical case of this rare disease came under my care in June, 1884. The patient was a woman, aged 54, a cook, who had always perfect health up to the preceding January, when the arms and inner surfaces of the thighs commenced itching, and she

*Treatment of Whooping-Cough by Small and Repeated Doses of Sulphate of Quinine.

felt hard little lumps in the skin. She became rapidly worse, and after trying many remedies, was sent to Harrowgate. She could get no sleep, even with powerful hypnotics, and her nervous system was completely broken down. The prurigo was situated on the upper arms to four inches above the elbow-joints; it was worse on the flexor surfaces; from the elbow-joints to the wrists, it was worst nearest the wrists. The legs were not so bad as the arms, but still were very typically affected from the knees to the upper third of the thighs. The skin was darker than natural, and thickened so much that it could not be picked up between the finger and thumb; its lines and furrows were deepened and widened, particularly so on the extensor surfaces of the wrists. The disease was much less abundant above than below the elbow-joints, which were not affected. The legs were not so severely affected as the arms, where I found the sign which Hebra gives as a certain diagnostic. On passing the hand over the skin, it produced a sound like a short-haired brush or packing paper, caused a prickling sensation in the fingers, and felt like a nutmeg-grater. The function of the sweat-glands was in abeyance. The patient's family history was good; she was a well preserved woman, with all her organs and functions normal. I ordered the sulphur water, before breakfast, in purgative doses, and the magnesia water at noon, as a diuretic, with a strong sulphur bath every second day. I also ordered the magnesia water to be used as a lotion as often as the patient wished. The progress of the cure was steady and satisfactory, and on July 16, the arms were well; the wrists almost so; the thighs also were very much better, but not so much so as the arms. There was no irritation even in the night. The patient returned to her work. The result of this case was very satisfactory. It proves the great value of sulphur water, and the powerful absorbent and softening influence it has over the very worst forms of chronic indurated skin disease. The relief of the itching I must attribute to the great soothing action the water has upon the nerve terminations. My patient walked into my study a year ago. She was perfectly well, with a healthy, though, in some places, a thickened skin.

Fifty Cases of Lacerated Cervix Treated by Silkworm Gut Suture and Iodoform.

Dr. R. Stansbury Sutton thus writes in the *Med. News*, July 3:

Two weeks ago I completed a line of fifty lacerated cervix operations. These cases were all done in about twenty-four months. Each patient was prepared as usual, or as Emmet teaches. The instruments, sponges, and ligatures were scalded and used directly from the bath when sufficiently cool. The lips were well denuded, sound tissue being sought for always. They were carefully approximated, and united with silkworm gut sutures, the ends left long. The cervix was then covered with a small teaspoonful of iodoform. The patient was put to bed; the catheter was not to be used unless the patient failed at the end of eight hours to pass water, and not again if it could be avoided. No douches were permitted until the sixth or more generally the seventh day, when a douche was given to clean the vagina preparatory to removing the sutures.

In forty-nine of the cases the temperature never exceeded 100° F., and in many of them 99° F. In one some sepsis occurred, and the temperature exceeded 100° F. All recovered; in one there remained for a short time a fistulous opening at the site of the upper stitch. In one the lower stitch cut out. Both were unilateral cases.

Silver wire and douches and catheter can give no better results, and this method of treatment is infinitely less annoying to the patients.

The large amount of iodoform has not given any trouble. Those who will follow me in this method will, I believe, find it an advantage over the method of silver sutures and frequent douches. They will get lower temperature, and these cases will require no skilled nurse.

Any ordinary attendant who will do only what she is told to do will answer as well as the best.

I will do fifty cases with silk and chemically pure powdered boracic acid. But better results than I have obtained in the fifty cases reported above can scarcely be expected.

Syrup Trifolium Comp. in Syphilis.

Dr. J. J. Garver thus writes in the *Med. Age*, June 25:

Case 1. W. D., æt. 27, laborer. Came to the dispensary May 1. Gave history of syphilis contracted six months previous. Copper-colored eruption on legs; throat and fauces one mass of mucous patches. Made one application of carbolic acid, and prescribed syrup trifolium comp., in tablespoonful doses, after each meal, with water. In a week he returned, much improved. Some

rheumatic pains yet remained. Patient improved remarkably, and in two weeks was like a new man. I am happily surprised at the good results of syrup trifolium comp.

Case 2. A. F., white, railroader, came to the dispensary May 18. Chancroid on foreskin, enlarged lymphatics in both groins and inside of left thigh. The latter suppurated and discharged copiously. Pains in bones, especially at night, quite severe. Ordered:

℞. Syr. trifolium comp., ℥iv.
Potassii iodidi, ʒv.
M. S.—Teaspoonful after each meal, with water.

Saw no more of the case for three weeks, when he came back to the dispensary, saying he never felt so well in all his life.

Case 3. E. T., female, æt. 20, sent for me, and on reaching the residence I found her in bed, suffering intense pain in both tibiæ. Both limbs showed copper-colored spots and nodes. Ordered hot applications locally, and syrup trifolium comp. with potassii iodidi, and in one week the nocturnal pains in the tibiæ had disappeared.

Have had splendid success in several other cases with syrup trifolium comp. alone. It is an excellent vegetable alterative, and in combination with iodide of potassium it acts marvelously in specific disease.

Radical Operation for Hernia.

An improved operation for the radical cure of hernia has for some time past been practiced by Drs. Svensson and Erdmann, surgeons to the Sabbatsberg Hospital at Stockholm. A ligature is applied to the neck of the hernia, and the sac is cut off below the ligature, the contents being previously examined by means of an incision into the sac and returned; or, if only omental, excised together with the sac. In congenital hernias the upper part of the sac only is removed, and where the large bowel is included in the hernia and adherent to the sac wall, this, after being separated from the surrounding tissue, is returned, together with the large intestine, and the rents of Poupart's ligament united by sutures. The dressing employed is iodoform and boracic acid, the wounds being washed with sublimate solution. Since this has been substituted for carbolic gauze, abscesses which used to occur frequently, have become rare. Of the forty-eight cases thus operated on, none of which were selected, thirty-eight were permanently cured—at least no return of the hernia occurred within six months; and in the cases where a return did take place, which amounted to twenty per cent., the condition was very much less painful and distressing than it had been previous to the operation. The Sabbatsberg Hospital has now been opened six years and a half, and during that time 300 cases of hernia have been admitted, about 200 of these being operated on with the knife; a milder procedure, consisting of alcoholic injections, being employed in most of the earlier cases. Not a single case proved fatal, though some of the hernias were very large, some reaching within three or four inches of the knee.

Radical Cure of Varicocele by Excision.

Il Bullettino of the Royal Academy of Medicine of Genoa (No. I., 1886), reports a case in which Professor Ceci successfully treated a large left varicocele by excising the dilated spermatic venous plexus. The patient, aged twenty-two, suffered great inconvenience in consequence of the enlargement. Under chloroform, an incision two and a half inches long was made on the left outer side of the scrotum down to the vein, the distention of which was maintained by an assistant exercising pressure at the external abdominal ring. With a director, the vas deferens and the spermatic artery were carefully isolated from the vein, which was secured with two catgut ligatures at the abdominal ring and near the testicle. The varicose venous plexus was then excised. The skin wound was closed with a catgut suture, a drainage-tube having been placed in the lower angle. On the eighth day, when the dressing was changed, there was some œdema of the scrotum; this part as well as the inner surface of the thigh, was the seat of carbolic eczema, and carbolic necrosis had attacked the edges and the bottom of the wound. These symptoms disappeared under borax and iodoform, and the patient made a perfect recovery. Professor Ceci considers that the technical progress in operations for varicocele due to the influence of asceptic and antiseptic precautions, justifies preference for excision of the vein over difficult and complicated methods.

Intestinal Antisepsis.

Dr. D. N. Kinsman thus concludes a paper in the *Jour. Am. Med. Ass.*, July 3:

I think we have arrived at bed-rock, and are now ready to formulate why mercury has been used and is likely to be used in all time, and also why it has done good and will

continue to do good. I think that I may draw the following conclusions:

1. Digestion is due to unorganized and organized ferments, *i. e.*, bacteria.

2. Dyspeptic phenomena are probably due to bacterial action, *i. e.*, fermentations.

3. In these fermentations, ptomaines, indol, skatol, phenol, etc., are formed as in putrefactions.

4. The presence of indol, skatol, and phenol is evidence of bacterial action, *a*, because in the meconium there are none of these products; *b*, they are absent in the stools of nursing children; *c*, in the urine of the newborn and nursing child there is no indican; *d*, when these children begin mixed feeding, bacilli appear, and with them indol in the stools and indican in the urine.

5. These bacilli, while causing putrefactions, produce poisons, which are normally destroyed in the liver, or stored therein, or excreted by the kidneys and bowels.

6. When the function of the liver is disturbed from any cause, so that the antiseptic action of bile is no longer exerted, the putrefaction and its products increase.

7. Mercurials, by arresting fermentations when in excess in the intestines, prevent the formation of ptomaines and auto-intoxication and supplement the action of the liver.

8. The beneficial action of mercury is due to its antiseptic properties.

9. Antiseptic medication is indicated in all cases when the indican is in excess in the urine.

A Case of Naso-pharyngeal Growth.

Before the American Laryngological Association, Dr. Samuel Johnston, of Baltimore, reported this case:

A child was brought to him on account of difficulty in breathing through one nostril. Examination showed that there was a tumor filling up the posterior part of the right nostril. After a short preliminary treatment, an attempt was made to remove the growth with the écraseur. A spray of a four per cent. solution of cocaine was employed. A cord was first passed through the nostril and brought out of the mouth, so that, if necessary, the nostril could be plugged without delay. The wire of the écraseur was applied without difficulty. When the growth had been cut through about two-thirds, the shaft of the instrument broke, leaving the wire and about three-fourths of an inch of the instrument attached to the growth. An attempt was made to apply a second écraseur, but this failed. After trying to remove the portion of instrument broken off, it was decided to wait a short time and allow the growth to slough. Four days later, the attempt to apply an écraseur was again made, and succeeded without difficulty. The tumor measured one and one-half inches in diameter, and was fibroid in character.

Iodinism.

After reporting several cases in the *Med. Herald*, for June, Dr. E. J. Kempf thus concludes:

The lessons to be deduced from these cases are:

1. Large draughts of water taken immediately after the drug prevents the more severe effects of iodinism by diluting the salt and causing its rapid elimination. And that if starch-water is not immediately at hand, pure water should be largely given to one poisoned with iodine.

2. That the tolerance of iodine varies greatly in different subjects. A dram of tincture of iodine caused one individual no inconvenience, and five drops of the same tincture caused active symptoms of iodinism in another.

3. That this variation makes iodine an unreliable remedy, and it should induce us to commence with the smallest dose allowable in any case—if the patient bears it well we can increase the dose; and besides, it is a well-known fact that the individual will become habituated to the drug, and the danger of inducing iodinism will be reduced to a minimum.

4. That the tincture of iodine is the preparation of the drug most likely to cause iodine poisoning by mistake, as only one drop more than is prescribed may be sufficient to cause iodinism. That the tincture ought never to be used internally, as there are other and more reliable preparations of iodine that may be used when the remedy is indicated.

5. That the children especially should be watched when taking any iodine preparation, though, as a rule, they bear the drug in proper doses as well as adults.

An Artificial Heel by Grafting.

At a recent meeting of the Academie de Medicine, M. Berger presented a patient in whom he was able to make an artificial heel by means of a large lump taken from the opposite leg. The graft succeeded completely, and the heel is now perfectly restored, but sensation has not yet appeared.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

CAREFUL INVESTIGATIONS.

A Dr. Kempner recently published in Germany a rather extensive pamphlet by which he endeavored to make arguments in favor of cremation. One of his main reasons, which he adduces as proof, why cremation should be generally adopted instead of burying the dead, consists in the fact that the possibility of burial of persons only apparently dead would be effectually prevented. There is no doubt that any individual whether really or only apparently dead, if exposed to the process of cremation, as carried out in modern times, will surely not be buried alive; on the contrary, any chance of revival is gone the moment the intense heat of the retort touches the body.

While we are decidedly in favor of cremation, we do not admit that the fear of being buried alive should be a reason to cause us to reject burial and to adopt cremation. There are two simple tests by which we can always convince ourselves whether a person is really dead or not. One test is the same that has been crowned with a prize by the French Government, which had for years offered a large reward for the discovery of any method, always applicable, always reliable, and one that may be practiced by the most ignorant. The method of determining actual death, which was considered by the French Government worthy of the reward, is the following:

When the fingers of a person supposed to be dead are fully extended, but kept near together, and if then placed in front of a candle-light in a dark room, a peculiar bright red color, due to the capillary circulation, will be visible where the fingers touch each other, if there is any life left. This test has thus far proved the most reliable.

The other is based upon the well known fact, that the muscles of a human being will never respond for a longer time to the strongest electrical current than for one hour and a half after death, while as long as life lasts, may its evidences be ever so little, the contractility of the muscles, if not affected by some forms of paralysis—and in cases thus affected, when death seems to occur, it always is real—remains.

We can, therefore, to-day easily convince ourselves whether death has really occurred or not, and though cremation is the preferable way of disposing of our dead, it is not necessary to prevent the burial of persons only apparently dead. But this Dr. Kempner, in his pamphlet, tells a number of horrible stories, altogether over twenty, of individuals who in various parts of Germany,

during the last forty years, were buried alive in some instances, and in others nearly buried. In some cases the grave-digger, while preparing a new grave, heard hammering and commotion in a coffin which had been placed in the ground but the day before; in others, everything was ready for the funeral, when the presumed dead body showed signs of life; in again others the individuals awoke in the vault and discovered to their terror the place they were in; in some the persons heard everything said about them, saw all that was done with them, and had to pass KNOWINGLY through all the horrible ordeal of being buried alive, without, however, their being able to utter one word, or to show by any sign that they were still living. These cases were not only mentioned in a general way; everybody's name was given, the village or city mentioned where the occurrence took place, and the page and number of the official register even was published.

Naturally under these conditions the pamphlet produced a great sensation amongst the people in general, and many became converts of cremation. But one physician, Dr. Max Breitung, of Berlin, could not believe that in this enlightened age, and in a state so far advanced in general education and science as Prussia—for nearly all the cases were said by K. to have occurred there—so many such horrible cases should have happened in comparatively so short a period and only so recently, without his ever having heard anything of them, and without the government having taken some steps to prevent the recurrence of such terrible accidents.

Patiently and thoroughly he went to work, and during nearly a whole year he corresponded with the police authorities, physicians, ministers, undertakers and others, residing in the places where the cases had been said to occur. He employed every possible means to get at the truth, and finally published the result of *his* investigations (*Deutsch. Med. Zeit.*, June 17, 1886).

And what had he discovered? That not in a single case could the truth of the story be verified. In some cases persons who had been living at the time of the said occurrence, and undertakers, who had done all the burial during that time, did not know a single word about it, had never heard of it; and the official register of deaths did not contain the name of the person buried alive. In other cases, all the evidence obtained in favor of the story was, that a relative of the party said to be buried alive had once heard that the person had nearly died from some disease, but had recovered. In another case the story referred to a person who had apparently been drowned, but had been brought back to life by the efforts of physicians.

We mention the whole only as a contribution to what rumor finally makes of a story. Dr. K. had obtained his information from newspapers and such sources, and without first convincing himself of the truth of the tales, had made use of them in a scientific argument. It is said that the youth of Berlin has ceased to use the name of Munchausen, when desiring to put a story down as manufactured whole, and that instead the name of Kempner is now used for the same purpose. Nobody will probably envy him for the notoriety he has thus obtained. Then we also learn another lesson, viz., not to publish facts without knowing them to be facts, for somebody in this enlightened age will discover the truth and announce it.

AN ATTEMPT AT POISONING BY NITRIC ACID.

An engraver, æt. 36, who for some time had shown symptoms of aberration of mind, for the purpose of committing suicide swallowed about five fluidrachms of fuming nitric acid of commerce. The most intense pains at once set in, and a physician prescribed 1½ ounces of Glauber salt, which caused a considerable amount of emesis. Twelve hours later he was brought to the hospital, where he came in charge of Dr. Richardière, who reports the case in the *Annales d' Hygiène Publique de Méd. Légale*, 1886, p. 88.

At the hospital the patient was made to swallow a large quantity of magnesia and milk. The following day he greatly complained of pain along the œsophagus, especially at every attempt at swallowing. Lateral pressure on the larynx caused no pain, but such backward did. There was no fever, but the local temperature in the epigastrium was 4° higher. No more vomiting. The lips were intact, the tongue was painfully swollen, velum and uvula were the same. The urine was brick red; on addition of sulphuric acid and green vitrol, it assumed a pink tint (due to the nitric acid), but this reaction remained only the first day. While the next day the local lesion evinced no change, the general condition of the patient and his state of mind were all that could be desired; he regretted the deed which he had committed, as he said, to escape from imaginary enemies—while the wound in the mouth slowly cicatrized, and the urine, always free from albumen, gradually returned to its normal condition, only swallowing re-

mained difficult and painful. As catheterismus of the œsophagus could not be practiced on account of the great soreness of the latter, the development of a cicatricial stenosis of the œsophagus may perhaps be predicted. The twelfth day the patient left the hospital.

Considering the mildness of the symptoms, the doctor is of the opinion that notwithstanding the saying of the patient to the contrary, the nitric acid was greatly diluted with water.

DELIVERY DURING HYPNOSIS.

A pregnant woman, aged 26, was admitted into the obstetrical clinic of C. Braun, in Vienna. Dr. Pritzl, who reports the case in the *Wiener Med. Wochschr.*, 1886, No. 21, says that it was accidentally discovered that she could easily be brought into a hypnotic state. The hypnotic sleep in her case set in rapidly and had no bad consequences of any kind. When, therefore, during the delivery the labor pains became very severe, he concluded to put her into the hypnotic state. He easily succeeded in doing so. The labor remained vigorous, the pauses became longer, and abdominal pressure continued to act; at the same time the os of the uterus dilated well and the delivery was happily concluded. The placenta was then delivered into the vagina and removed by the hand. On awakening, the patient felt very strong and did not remember any pain.

A remarkable fact was that abdominal pressure was brought about by reflex, for the patient being totally unconscious, no action of hers could have excited the pressure. Very little blood was lost during the delivery.

NOTES AND COMMENTS.

Deviation of the Nasal Septum.

Although the introduction of the laryngoscope nearly thirty years ago rapidly developed a new era in the diagnosis and treatment of diseases of the larynx, it is a much shorter time since greater attention has been paid by specialists to affections of the nose and its adjacent parts. In the July number of *The American Journal of the Medical Sciences*, Dr. J. W. Gleitsmann, of New York, in an instructive paper on deviation of the nasal septum, points out the different important functions performed by the nose in the human economy, and the results of interference with these functions. The upper part of the nasal cavity, the olfactory region, presides over the sense of smell, whilst the lower one, the respiratory region, is the normal way for the air during the act of respiration. Interference with this natural channel leads to mouth-breathing, with its manifold subsequent evils. When the air passes through the nose, it is not only cleansed and moistened, but it also reaches the lungs much warmer than when breathing is going on by the mouth. Nasal respiration with closed lips further exerts a negative pressure of two to four milligrammes mercury in the oral cavity, by which the tongue is drawn to the hard palate, and the muscular action, maintaining the position of the lower maxilla, greatly assisted. The nose also acts the part of a resonant chamber for the human voice, and nasal obstruction imparts to it the so-called dead character, described in Meyer's paper on adenoid vegetations. Finally, it is due to the anatomical relations of the nose to the eye and ear that cases of catarrhal conjunctivitis, and lachrymal fistula, frequently only heal when co-existing nasal affections are relieved, and that the latter are, in an overwhelming number of instances, productive of aural disease often of the severest kind. Aside from the symptoms of nasal stenosis in a greater or less degree, deviations of the septum, Dr. Gleitsmann points out, are apt to cause disfigurement of the face, and also have some relation to the bony structures of the head, which he fully explains. The pathology, etiology, symptomatology, and treatment of these deviations is fully discussed.

Acute Carbolismus—Accident or Suicide?

Dr. E. Zurcher was called one morning to a porter, æt. 47, who was well known as a quiet and respectable man, and whom he had met only the evening before in perfect health. We found him lying on the floor, unconscious, breathing heavily, and cyanotic. The pulse was thread-like, the dilated pupils reacted but sluggishly, the teeth could scarcely be forced apart, and on the lower lip blood trickled down from a small wound caused by a bite; death occurred within a few minutes. Shortly before, a neighbor had seen him occupied with his usual labor.

Post-mortem.—Dura partly grown together with the bone, and pia with the cerebrum; between dura and pia a small amount of œdematous fluid, the same in the lateral ventricles, and in the left corpus striatum an interstitial cicatrix. Tongue pale, not between the teeth, free from erosions; buccal m. m. and lips same. The œsophagus, in its

lower portion, light-brown red; in its upper, rose-red. The stomach contained nearly five ounces of an opaque, thick, chocolate-colored fluid, with an intense odor of carbolic acid. The m. m. of the stomach over its whole extent strongly hyperæmic, uniformly of a dirty red-brown hue, though still darker in the fundus. Ridges greatly swollen, partly erosed, and showing grayish-white "burned" places; stomach greatly contracted. The duodenum evinced the same discoloration and ulceration, but lessening in intensity the further down; kidneys strongly hyperæmic, and with a very intense odor of carbolic acid. Bladder contains a little yellowish-brown concentrated urine. Blood black. Cause of death undoubtedly, therefore, acute poisoning by carbolic acid.

Later, a bottle, yet half filled with carbolic acid, was found in a closet in the room. In favor of suicide were the following points: The large quantity of the poison, its strong odor and easily-recognizable taste; the fact that lips and tongue were intact, showing that the fluid must have been thrown back into the pharynx under some sudden impulse; the bottle had the correct red-colored label, and the deceased never was a drinker. The abnormal conditions of the brain also prove the probable existence of a melancholic depression at the time of the deed.

Fatal Hemorrhage from Injury of the External Female Sexual Organs.

A tripara, æt. 30, about two and a half weeks before her expected delivery, while fastening a curtain to the window, fell from a chair. Severe hemorrhage, violent labor pains, and pains in the abdominal regions, at once set in. Ere medical aid arrived, about half an hour after the accident, death occurred. An operation to save the fœtus could not be performed for reasons not stated.

The autopsy revealed twins in the nowhere injured uterus; the placenta was all over attached to the uterine wall in a normal manner; in the uterus were found about 25 ounces of fluid. The cause of the hemorrhage was a tear in the vulva 3 ctm. long and ½ ctm. deep, beginning at the clitoris, dividing its right half, and running parallel with the right descending ramus of the pubic bone, ending in the labium minus. The wound showed no larger vessels, but the open spaces of the torn cavernous tissue. The tear was probably produced by the external genitals striking against the edge of the window-sill, the soft parts being pressed violently against the bony pelvis. The case finds its complete analogy in four others reported by Kaltenbach, Leopold, and Braun. In each of these, by striking on a hard, unyielding substance, a tear resulted, passing through the clitoris and labium minus, and parallel the pubic bone. In all the great hemorrhage stood in no relation to the size of the wound, and was of a parenchymatous nature.

Passage of Pathogenic Microbes from the Mother to the Fœtus.

Kaubassoff has made a series of investigations to determine the cause of the hereditary nature of certain infectious diseases, and he obtained the following results:

1. The bacilli of anthrax always pass from the mother to the fœtus.

2. The longer the period intervening between inoculation of the mother and her death, the more bacilli will be found in the fœtus.

3. More bacilli pass over of the virulent than of the milder forms of anthrax.

4. Morbid conditions of the membranes, of the placenta, and of the fœtus (its death), prevent the passage of the bacilli from the mother to the fœtus.

5. Inoculation of the mother with too strong anthrax vaccine almost invariably causes the death of the fœtus.

6. Renewed inoculation with virulent lymph of the pregnant animal, which had previously been inoculated with a weakened virus, also almost always produces the death of the fœtus; those surviving one inoculation die from virulent lymph, or in other words, the fœtus has not been sufficiently vaccinated by the parent to insure its impunity from the disease, a result which might have been foretold after experiments had proved that bacilli of weakened virus pass far less into the fœtus than those of the virulent kind.

Cirrhosis of the Liver in a Boy.

That a cirrhotic liver may arise from other causes besides the immoderate use of strong alcoholic drinks, is daily proved more.

In the *Revue Mens. des Malad. de l' Enfance*, 1886, p. 166, Dr. M. Lavallée reports the following case: A boy, æt. 5½, who had been ailing more or less since the eighteenth month of his life, was brought to the Children's Hospital suffering from ascites in a high degree. While the group of symptoms as a whole greatly resembled that of tubercular peritonitis, the great dilatation of the abdominal veins, and the positively negative

result of physical exploration of the lungs, caused the suspicion of the presence of another still graver malady. A positive diagnosis, however, intra vitam, could not be made.

The child died, and the autopsy revealed an atrophic, granular liver; the microscopical examination showed the acini compressed by a great mass of cicatricial interstitial tissue, and diminished by partial destruction of the liver cells. The spleen was enlarged and very hard. The kidneys, though microscopically having the appearance of normal organs, revealed in many slices the microscopical picture of interstitial nephritis, while others seemed healthy. The etiology remains obscure, as the author could not discover any pathogenic element.

Communication between the Stomach and Transverse Colon.

Mr. Jeffreys showed this specimen to the Sheffield Medico-Chirurgical Society, from a man aged fifty-four, a retired publican. Pain over and enlargement of the liver were first noticed in May, 1884. Later there had been several attacks of profuse offensive expectoration, and they lasted a considerable period. Emaciation steadily increased. On February 16 last he had a severe syncopal attack, and shortly after stercoraceous vomiting set in; this was preceded by severe diffused abdominal pain. He suffered a great deal from constipation, and enemata were used. On February 27 he passed a large piece of necrosed tissue, accompanied by hemorrhage. He died on March 2, from exhaustion. At the post-mortem a large cavity containing pus, and extending from the lower part of the transverse colon to the under side of the diaphraghm was found; the spleen formed the outer, and the posterior wall of the stomach, the inner, boundary. The stomach, through an opening in its posterior wall, communicated with this cavity, as did also the posterior part of the transverse colon; there was also an opening (from the abscess cavity) through the diaphragm, and at this point the left lung was adherent.

Tests for Albumen in Urine.

The "Albumen Test Committee" of the Clinical Society of London, presented recently (*Brit. Med. Jour.*, June 5,) a report of the work accomplished by them, which, according to custom, was received without discussion. In it, the committee briefly reviewed the various modes of testing for urinary albumen, etc., in common use, and compared in turn Dr. Oliver's test-papers, Dr. Johnson's picric acid method, the potassio-mercuric iodide and acid, Dr. Pavy's pellets, the acid brine method, picric acid and brine, the acetic acid, and the nitric acid methods. After careful consideration and experiment, the committee arrived at the conclusion that the papers of Dr. Oliver possessed advantages in the way of portability and delicacy of reaction over the other similar preparations; but, apart from the question of easy carriage and compactness, they described nitric acid as being most reliable and delicate. All the methods, however, were said to be respectively useful for the determination of different proteids in the urine.

The Treatment of Diphtheria by Bromine and Iodine.

Dr. Kramer, of Amsterdam, has found a new remedy for diphtheria in the form of a mixture of bromine and iodine, with which he has made some remarkable cures (*Centralbl. für Klin. Med.* for December, 1885). He uses the remedy also as a prophylactic, brushing the throat night and morning during an epidemic, first with one and then with the other of the following solutions:

1. Bromide of iodine, bromide of potassium, of each 1 part; distilled water, 200 parts.

2. Carbolic acid, 1 part; rectified spirit and glycerine, each 25 parts.

The same solutions are used for the disease itself, but the first may be increased to double the strength, and is applied every hour, the second being used three times a day. The treatment is concluded by blowing benzoate of sodium into the throat three times a day, administering the same drug in doses of two to four drachms, according to the age of the patient, and keeping the bowels open.

Interesting Case of Twins: Version.

On May 10, Dr. A. Crosbee Dixey (*Brit. Med. Jour.*) was called to attend Mrs. R., multipara, aged 36, in labor. On examination he found a head presenting, the child (male) after a time being delivered in the normal way. The pains now entirely ceased; but the uterus, from abdominal examination, was still found to be enlarged; and, on vaginal examination, another head was felt presenting anteriorly, and a foot posteriorly.

Two hours having intervened from the birth of the first child, and no pains having come on, although ergot was freely used, as the patient was becoming exhausted, he rup-

tured the membranes, and performed podic version, delivering her of a second living child, also male. The uterus being compressed, the two placentæ were expelled together, no hemorrhage following, notwithstanding the large bleeding surface exposed by the separation of the two placentæ and the previous inertia of the uterus.

It is interesting to note the family history. Her husband's mother had twins, his sister had twins, and her own mother had twins, and she herself had twins at her two previous labors.

The points to be noticed in this case are:

1. The family history pointing to the fact of twin births being hereditary.

2. The value of compressing the uterus externally where post-partum hemorrhage may reasonably be expected.

3. The abnormal presentation of the second child.

The mother and children both did remarkably well, her temperature never being above normal.

Constipation.

There is always something to be learnt about this exceedingly common and annoying complaint. Dr. Arthur V. Meigs recently related the histories of seven interesting cases before the College of Physicians which teach several valuable lessons. They warn us never to diagnose an abdominal tumor until we have purged the patient. They teach us that constipation can cause a fever which the best of us may be misled into considering as typhoid. Again, as Dr. Da Costa said, constipation may cause a relapse in convalescence from low fevers, and he even says that in some of these cases there may be well-developed typhoid fever symptoms with rash, due to constipation, which will disappear when the bowels are moved. So that, on the whole, it would seem to be very important to look carefully after our patients' bowels in all cases.

A Case of Syphilis Cut Short by Sulphur-Baths and Mercurial Inunctions.

Dr. P. J. Kalashnikoff, of Piatigorsk records (*Proceedings of the Piatigorsk* (Russia) *Balneological Society*, March 4, 1886, p. 8,) the case of a soldier who was admitted with a characteristic induration on the penis at the side of a recently healed primary ulcer, and with a marked universal adenitis. After ten sulphur-baths the sclerosis became exulcerated. The ulcer did not yield to local medication. Under the influence of the inunction of grey mercurial ointment (ten frictions of one scruple each and ten of half a drachm), and sulphur-baths (fifty-one), the ulcer rapidly healed, and sclerosis and adenitis disappeared. His skin and mucous membranes remained healthy. Not a single syphilitic symptom made its appearance subsequently (more than six months passed from his cure up to the date).

Iodoform and Nitrate of Silver in Indolent Ulcers.

Dr. Maethe, writing in the *Norwegian Medical Archives*, recommends a combined application of iodoform and nitrate of silver to indolent ulcers, fistulæ, and all badly healing granulating surfaces. He first applies a thin coating of powdered iodoform, and then cauterizes with nitrate of silver, after which more iodoform is applied. There are formed in this way nitric acid, iodoform, and iodide of silver, and their nascent condition effects a great change in the conditions of tissue life. The advantages of this method of treating ulcers are that the action is purely local, and that the cicatrization of the surface is effected under an antiseptic covering.

Osmate of Potassium.

Merck, of Darmstadt, has prepared the osmate of potassium to obviate the use of osmic acid, which is so irritating to the respiratory organs, and so hygroscopic. The *British and Colonial Druggist* is informed that an English firm has also manufactured the sodium and lithium salts. The potassium compound is said by Wildermuth to have proved beneficial in some cases of epilepsy, the daily dose being one dozen pills, each containing $\frac{1}{6\frac{1}{4}}$th of a grain in combination or alternation with bromide of potassium. A 1 per cent. solution of the potassic osmate has also been recommended in the treatment of goitre, neuralgia, tumors, and other diseases.

Oxide of Zinc Ointment for Gonorrhœa.

In the *Albany Med. Annals*, for June, Dr. O. D. Ball claims excellent results from this treatment. Of fifteen cases the average time of treatment was a little over four weeks; the longest any one case was under treatment was eight weeks, the shortest ten days.

The ointment is placed around the constricted portion of a bougie, which is passed down to the prostatic portion of the urethra, rotated, and slowly withdrawn. The appli-

cations are made twice daily. The ointment is thus prepared:

℞.	Zinci oxidi,	ʒiij.
	Adipis,	ʒiij.
	Cerati simp.,	ʒij.

Diseases of the Period of Dentition.

How very commonly do we hear the remark that this and that disorder of early childhood is "due to teething," when, judging that it will right itself, no heed is paid to it. It is well that Dr. W. C. Barrett has called attention to this fatal negligence in the *Med. Press of Western New York*, where he strongly gives us the good advice that even though many of these disorders may be due to dental irritation, yet we should relieve them before it is too late, and before our criminal negligence is responsible for the life of some poor little innocent.

Chinese Remedy for Hydrophobia.

In the report of the Presbyterian Mission Hospital at Ung-Kang-Phu, it is stated that the Chinese have the firmest reliance on a native remedy for preventing the development of hydrophobia in a person bitten by a rabid dog. The patient takes a pill consisting of nux vomica and pounded beetles; the beetle has much the same properties as Spanish fly, and the dose is repeated until the urine becomes bloody. All danger is then considered to have passed. It is hardly necessary to add that no statistics are forthcoming as to the success of the treatment.

A Singular Coincidence in the History of Cancer.

Before the Baltimore Academy of Medicine (May 18), Dr. J. J. Chisolm related a singular coincidence that recently came under his observation. It was a case in which he was called upon to amputate a cancerous external ear from an old man æt. 80. The coincidence rests in the fact that this man had had two wives, both of whom had had cancer, and both of whom had died as the result of the operation. Dr. Chisolm's patient, however, is still living.

Correspondence.

Cocaine as a Remedy for "Rose Cold."

Eds. Med. and Surg. Reporter:

For the last seven or eight years I have suffered some personal experience with the form of hay fever commonly denominated "rose cold." It appears about the 20th or 25th of May, and continues for four weeks or thereabouts. Heretofore I have found no relief from any of the numerous remedies in vogue, the symptoms occasioning great and often well-nigh intolerable distress during the period of their continuance. This season I had resort to cocaine with entire satisfaction; the strength of the solution employed being a four per cent. A solution of this strength I found to be as effective and as lasting as a six or greater. A two per cent. proved unsatisfactory. The best mode of application I found to be by simple instillation into each nostril of six or eight drops by means of an ordinary medicine dropper. Oily solutions were found to be ineffective. The effect was felt within five minutes, and lasted on an average two hours. I have no doubt whatever of having experienced decided constitutional effects from absorption of the remedy into the system, and this suggests the danger from its long-continued use in the more protracted form of hay fever. A person using cocaine several times daily for a period of a couple of months or more will run some risk of acquiring an irresistible liking for its effects, and may experience some difficulty in breaking off. In my own case it caused the oft-mentioned feeling of well-being, decided diminution of the sense of fatigue on exertion, as well as increased wakefulness. I should caution hay-fever patients against keeping up the continued influence of the drug, but should insist upon its being reserved for the more aggravated paroxysms. In the case, for instance, of a public speaker, it is very convenient as well as comforting to have at hand an agent which will promptly and surely enable him to appear at his best for a given time, though he be given up to lachrymæ and sternutation at others.

It is probable that with regard to cocaine, as well as many other drugs, there will be found to exist great variation in individual susceptibility to its effects. The subjects of certain forms of nasal catarrh, especially of the hypertrophic forms, will quickly experience constitutional effects from absorption of the drug, and these should be cautioned against yielding to the temptation to its too frequent use. Cases are already reported of addiction to the cocaine habit; but whether it shall be found to be one very difficult of abandonment, remains to be demonstrated by further experience. In the meantime it is the part of wisdom to prescribe cocaine as we would morphine, always exercising caution and enjoining upon the patient the duty

of self-control, in order that there be little risk of a great blessing being made a curse.

Youngstown, Ohio.

NEWS AND MISCELLANY.

Ovariotomy in Russia.

Dr. Matveëff has published a large amount of information on the subject of ovariotomy in Russia. The first operation in the country was performed by Vantsetti in Kharkoff, in 1848, but was attended with a fatal result, Professor Krassovich being the first to perform a successful case in 1862. Altogether the author has collected accounts of the work of ninety-six Russian surgeons. The total number of operations was 696, of which 213 ended fatally; this includes 98 double cases with 32 deaths, 16 pregnant cases with 2 deaths, 50 dermoid cyst cases, only one of which was unsuccessful, and 42 cases of malignant tumor of the ovary, of which 26 were fatal. The ages of the patients varied from fourteen to sixty-eight. Of the pregnant cases, one was as early as the second month and one as late as the ninth; of the 16, 6 miscarried, and 2, as stated above, died. Secondary ovariotomy was performed six times, only one of these cases being unsuccessful. Most of the fatal cases were due to peritonitis; of the total number of deaths (213), this accounted for 133, collapse for 14, exhaustion for 12, and internal hemorrhage for 10. The general percentage of deaths was about 30. That of different operators who had a record of 25 or more cases varied from 42.9 to 8.8 (Slavianski) and 7.7 (Rein). According to a letter by Prof. A. Y. Krassovski, which is published in Sir Spencer Wells's work on Ovarian and Uterine Tumors, it is stated that up to 1882, 302 cases had been performed by Russian surgeons, with a mortality of 44 per cent. Dr. Matveëf is to be congratulated on his later and more successful statistics, which show that Russian operators are becoming more and more successful in their ovariotomy results. As to the places in which the operations were performed, nearly all were done in university towns: thus, St. Petersburg claims 294, Moscow 110, Kieff 59, Warsaw 52, Kharkoff 40, Kazan 28, Dorpat 25, and Helsingfors 4. Of the remaining 84, 46 were performed by Dr. Kuznetski in Nijni-Tagilski in the province of Perm, and 18 by Dr. Ikavitz in Tambova.

Bismarck and His Doctor.

The *London World* says Prince Bismarck is again indisposed, it is said, and that means work for Professor Schwenninger, the Prince's doctor. Schwenninger is the Roose of Berlin. Munich was to him what Brighton was to our English rising medico, and Bismarck's eldest son was his discoverer. This gentleman having had some sixty or seventy pounds' weight taken off him, and having been brought out of the very back teeth of death by following Dr. Schwenninger's advice, suggested that his father should also become a patient. The Chancellor was willing, but he could not go to Munich, and the doctor could not leave his practice there without a *quid pro quo*. The quid—several hundred quid—was found by his appointment to a Professorship in Berlin, which he now holds, in addition to an enormous private practice. He sees Bismarck daily, has brought him into perfect health, and has so tamed the tiger that the former periodical explosions in the Reichstag have entirely ceased, and there has been no change in the government since Schwenninger has had charge of the Chancellor's digestion. Diet, not medicine, is what Professor Schwenninger swears by. No drugs, no mineral waters, no "kur" of any kind. Eat of only one dish, no matter what that may be. Oysters, lobsters, beef, mutton—eat your moderate fill of that, but touch nothing else at a meal; no vegetables, save perhaps a little salad, no sweets, no savories, and do not touch one drop of liquid until half an hour, in some cases an hour, after your meal is ended. There is the *crux* for those who like Chablis with their oysters, Madeira with their turtle, Marcobrünner with their fish, and D. and G.'s Gold-Lack with their first entrée. One dish only, and no drink until long after the meal is over. What does Lucullus—what does Sir Henry Edwards, of the statute—think of that?

Buried in Chains.

The *Brit. Med. Jour.* says that some particulars of the mode in which the lunatics among the Boers of South Africa were treated in the early part of this century have been brought to light in a curious manner, and are reported in *The Colonies and India*. A new Dutch Reformed church is being built in Graaf-Reinet; and, while excavating the foundations of the west transept. the workmen came upon several old graves. As it had been resolved to place all the human bones found in a coffin, the workmen were

taking them up for that purpose, when, to their surprise, they found the leg-bones of one skeleton inside two very heavy iron rings, connected by a bar about twelve inches in length, the whole weighing thirteen pounds and a half. At the other end of the grave was a heavy iron ring, or collar, and close to it an iron bar about eighteen inches in length, with a small ring at each end, which had evidently been used instead of our modern handcuffs. How such rings had been fixed to the ankles of the unfortunate wearer, is a question which might puzzle some of our blacksmiths. On the question, "Who was the possessor of the interesting manacles?" speculation was rife, when the following solution of the difficulty was given by an old lady resident of Graaf-Reinet, now bordering upon ninety, who states that she distinctly remembers, when about thirteen, coming into town from the Sneeuwberg, and seeing a maniac, named Koekemoer, heavily manacled, allowed to go about the streets; a perfect terror to little girls, who would hardly venture outside the door for fear of meeting him. Sometimes he was knee-haltered by a chain fixed to an iron collar about the neck, to prevent his getting into mischief. At other times, he might go erect, having only chains on hands and feet. If the question should be raised as to the improbability of burying such an object of pity with chains and all, it might be answered that a government or a public that could thus treat him during life would find little scruple in saving themselves the trouble of removing, after death, such heavy iron rings as have been dug out of the old graves.

Young Doctors Must Wait.

A. G. Haygood thus addressed the last graduating class of the Atlanta Medical College (*Atlanta M. and S. Jour.*):

Young doctors, there is no help for it; you must practice on us of the laity before you can become really practical physicians. We will protect ourselves as long as we can. While the "old doctor" lives and is available we will, if we get sick, send for him. When we can do no better, we will send for you. Don't worry at this; it must be so; it is our only defense; you will have your revenge soon enough. The old doctor will die some day, or he will be too busy to come; something will befall us; the attack will be as sudden as severe; we must have your help or none. We may have laughed at you, and in our folly may have vowed that we would not send for you to treat a sick dog; but for all these follies of ours we will with desperate resolution send for you, trusting to a merciful Providence to help us through. (And we will trust Providence the more readily when we see even the young doctor, as badly scared as his patient, at the bedside). If we die you can explain it; if we get well we will sound your praises, even if we are slow in paying your fee.

If you kill a good many of us while really learning the practical part of your business, don't take it too much to heart, or throw your sign in the well, as Dr. Sims did after killing two or three patients.

Put it in the Cupboard.

"Reminiscences of the Court and Times of King Ernest of Hanover" have just been published, and are very interesting reading. They contain many surprising and characteristic stories of the crafty old king when he lived in England. When the physic arrived that the doctors had prescribed for him, he invariably said, "Put it in the cupboard," "Put it in the cupboard;" and again and again it was, "Put it in the cupboard." Not one drop was touched. Starving and patience were the only remedies resorted to. At last his majesty got his good turn, and began to feel that he could eat again with a relish; and by degrees nature flung off the disorder, whatever it was, which had run its course. His majesty was up and dressed early and at business. "Get all those bottles, powders, and pill-boxes out of the cupboard," he said, "and range them in a row round the room." It was a very small room, and they almost made a circle round the walls. The doctors came in smirking and smiling, and congratulated the king upon being up again and looking so well. "Yes, doctors," said his majesty, "thank God it is so. But look there—count it up; don't you think if I had taken all that d—d stuff I should have been dead long ago?"

Verruga; A Peruvian Fever.

The Lima Academy of Medicine has determined to make as many inquiries and observations as possible, in order to elucidate the natural history of a terrible Peruvian disease, known as verruga, which is thought to be identical with the fatal "Oroya fever," which many years ago carried off many of the work people employed on the railway across the Andes. Quite recently, a medical student, named Daniel A. Carrion, with ill-advised zeal for the advancement of science, inoculated himself with verruga, in the Dos

de Mayo Hospital, hoping to be able to gather some new facts about the disease, for the special purpose of enriching a dissertation he was writing on it for his approaching graduation. Some facts were certainly obtained; but, sad to say, at the cost of the life of the zealous experimentalist, who died thirty-eight days after inoculation, his symptoms being adynamic pyrexia, general dermatitis, and a morbid change in the blood, resembling leucocythemia. The period of inculcation was twenty-three days. His self-inoculation was quite unauthorized by his teachers, who naturally deeply deplore so sad a termination to the career of a most promising student.

The First Bacteriologist.

From the *Med. Record* we learn that in the year 1726 a quack, Boile by name, made his appearance in Paris, and promulgated a new theory of disease. All maladies, he said, were due to the presence of animalcules in the tissues; and all that was necessary to effect a cure was to introduce other and stronger animalcules, which would destroy the disease-producers. He had, he claimed, a large supply of the superior and curative animalcules, and would dispose of a sufficient number of them to any one who stood in need of their services and would pay for them. Of course he found plenty of customers, and soon drove a thriving business. But he came to grief. He used to demonstrate under a magnifying-glass the action of his remedies. He would take a little blood from the patient, and putting it under the microscope, would exhibit to his awe-struck visitors a number of hideous forms which were the cause of the malady. Then he added a drop of his special culture, and away would go the wicked animalcules, leaving the field clear. Some incredulous fellow, however, examined into the matter a little too minutely, and discovered that the microscope had a false bottom, and the battle of the animalcules was nothing but a painted show. This discovery had the same effect upon M. Boile that his remedy had upon the germs—he disappeared with amazing celerity.

Tossed by a Spanish Bull.

A recent number of *El Genio Médico* contains an article by Dr. Rodolfo Mauricio, of Pinoso, complaining of the dangerous habit of allowing bulls to go about the streets with merely a rope round their necks, and giving an account of a serious accident which occurred opposite his own house. A fête was going on, and a bull with a rope round it was coming along the street, when a young man who was a farm laborer and accustomed to cattle, thinking doubtless that it was only an ox he had to deal with, endeavored to turn it back by standing in front of it. The animal ran at him and tossed him about a yard high. The man on falling was deadly pale, but managed to raise himself and walk into the priest's house, where he was found by Dr. Mauricio a moment afterwards, lying on his back, a small stream of blood trickling from his left side. Death occurred in a very few minutes. At the post-mortem examination it was found that the horn had entered below Poupart's ligament on the left side, traversing the left iliac fossa, and had penetrated the bifurcation of the inferior vena cava. An immense quantity of blood was found in the abdominal cavity, the obliquity of the wound preventing much from flowing out.

The Social Evil in Liverpool.

Two tables in the head constable's annual report are devoted to statistics of the social evil in this city. Captain Bower remarks that as the law confers no power on the police to visit houses of ill-fame, the returns must in a great measure be conjectured. The number of houses suspected to be brothels is 440, and of women supposed to be prostitutes 1165, exclusive of those known to be in gaol. Under the vagrant act there have been 2890 cases against prostitutes. The number of women supposed to be prostitutes and taken into custody for disorderly conduct in the streets was for the year 2275 persons, 5279 arrests; 1992 persons convicted, 4372 convictions. These numbers will not appear excessive in so large a city as this; but they suffice to show that the present laws have little effect upon either brothels or prostitutes, though possibly some reduction may be effected by the criminal law amendment act.

A Teetotaller's Fatal Mistake.

An inquest was recently held in London on the body of John William Harris, aged sixty-three, a cab proprietor. The widow of the deceased stated that he had been a teetotaller for a number of years. Some months ago he attended a temperance lecture, and it was there stated that ammonia was the best substitute for alcohol. As he had a severe pain in the chest he thought he would take some. There was no trouble in getting it, as

they always bought a quantity from an oil shop to make up for oils for the horses. He took a tablespoonful, which took his breath away, and she then fetched a doctor. Dr. Norman Kerr stated that he was called in to see the deceased on April 5, and found him in great great agony, the mucous membrane being quite destroyed, and on Sunday night he succumbed to the effects of the poison. The widow said her husband did not think it was poison, as one of their horses took some by mistake about two years ago, and was alive now. The jury returned a verdict of accidental death.

Dio Lewis.

The *Medical Age* says:

Dr. Dio Lewis is dead. His life was chiefly devoted to the dissemination of a knowledge of personal hygiene among the masses, and, doubtless, it was not altogether spent in vain. He was a cremationist, and gave the following directions in regard to the disposition of his body: "Although I am averse to the somewhat unpleasant notoriety which, as yet, cremation involves, my very strong conviction is that it is the right disposition of the dead. I leave directions that my body shall be cremated, and that the ashes shall not be put into an urn, but into the earth, over which my wife may lovingly plant forget-me-nots. I direct, also, with my dear wife's assent, that all funeral parade and expense shall be avoided, and that my remains be placed in a pine casket for removal to the crematory. I desire, also, that no flowers may be sent by my friends."

A Chloral Hydrate Band.

On February 8, at the St. Petersburg District Criminal Court, a sensational process of a band of robbers was concluded. The band included three peasants and a *feldsher* (medical assistant) named Lantchinsky. Their operations consisted in drugging a hackney-coachman (*izvoshtchiks*) with chloral hydrate dissolved in *vodka* or in beer, or sometimes with tincture of opium; and in subsequently appropriating the horses, carriages, purses, etc., of their victims. Five separate crimes of the kind had been traced out, two of the victims having died from an overdose of chloral. Lantchinsky and another chief accomplice, named Kutiloff, were sentenced to twelve years of penal servitude each; a third member to eight years; and a fourth, to deportation to Eastern Siberia.

The Lyons Girl Silk Workers.

In an article of No. 41 of the *Lyon Médical*, Dr. Augagneur draws attention to the deplorable condition of the girl apprentices, who, drawn chiefly from the healthy regions of the Alps and Savoy, are subjected to a life of hard labor under the most unsanitary conditions. Overcrowded into small abodes under the *patrones* to whom they have been consigned, they live and sleep in unventilated rooms, passing long hours of labor, even extended sometimes on Sundays, and fed upon a most insufficient diet. The consequence is that the hospital of the Croix Rousse exhibits a greater mortality from phthisis than any other hospital in Europe, a third of its mortality being due to this cause. Against this state of things no legal remedy exists, the laws which supply inspection and control only having power in the large workshops, and not applying to the wretched abodes in which these girls work.

Food Analysis in France.

The Académie des Sciences has a laboratory in Paris for testing the quality of food and drink sold in that city. Specimens of wine, beer, cider, milk, chocolate, coffee, tea, etc., are examined, colors used on toys and in confectionery, pork suspected of being affected with trichinosis, etc. Analysis to determine whether the article presented is free from adulteration is made without charge; but a small fee is charged if it is required to determine the proportionate composition. There are twenty inspectors who visit taverns and groceries, provided with microscope and simple chemical tests, and examine many articles of merchandise on the spot, only taking to the laboratory such articles as afford some evidence of adulteration. Twenty-five chemists are connected with the laboratory, each one having his own department. About 25,000 samples are analyzed annually at an expense of about $40,000.

Breathing Cold Air in a Warm Room.

An apparatus is advertised in Europe by which a person is enabled to breathe the air from without while sitting in-doors in a warm room. It consists of a simple tube, communicating through the window with the external air, to one end of which an attachment to fit over the mouth and nose is attached. The inventor claims that, as tubercle bacilli are destroyed by a low temperature, so pulmonary phthisis may be cured by breathing frosty air through this apparatus.

Personal Journalism,

Dr. Shrady, editor of the *Medical Record*, continues his personalities in the pages of that journal. Before he prostitutes its columns to such purposes, he had better look over his own record, and reflect by what discreditable means he forced himself into General Grant's case, the story of which we could tell if we felt like imitating his example.

Medical Common Sense.

Dr. C. A. Allen closed his paper before the New Hampshire Medical Society with the following words:

"The time is coming when there will be no sects among educated physicians. The present war between the friends and opponents of the National Code but points the way. It will not be this year, nor the next. It will be when the world has grown wiser and has learned to value at its true worth any creed that uses its name as an advertising medium only. It will be when elementary medicine is taught in our common schools; when common sense shall reign in the minds of the people and they have learned that *pathy* does not make the doctor. It will be when our lawyers, our ministers, and our teachers shall add a general knowledge of medicine to that of their calling. It will be when doctors depend upon their profession rather than to prop it up with statutory laws."

Salt in Nevada.

If the salt formations of Nevada were in railroad communication, there would be no market in this country for the foreign article. In Lincoln county, on the Rio Virgin, there is a deposit of pure rock salt, which is exposed for a length of two miles, a width of half a mile, and is of unknown depth. In places, cañons are cut through it to a depth of sixty feet. It is of ancient formation, being covered in some places by basaltic rock and volcanic tufa. The deposit has been traced on the surface for a distance of nine miles. It is so solid that it must be blasted like rock, and so pure and transparent that print can be read through blocks of it a foot thick.

Parisian Fish and Parisian Gutters.

The itinerant fishmongers of Paris, in order to supply their customers with well cleaned fish, wash quantities of soles, whitings, plaice, etc., in the gutters, which are plentifully supplied with water. People who have the advantage of living in the vicinity of a good flowing gutter can frequently observe these sanitary precautions, and are thus forearmed and forewarned. Others, in this respect less fortunately placed, constantly purchase, in confiding innocence, fish cleaned in gutter water flowing through Paris streets, and devour the same, prepared with that skill for which the French cook is famed, a skill which may conceal bad flavors, but cannot protect the consumer against the evil results of devouring contaminated food.

Items.

—The American Rhinological Association will hold its fourth annual meeting at St. Louis, Mo., on the 6th of October next.

—Professor Virchow recently completed the thirtieth year of his occupancy of the chair of Pathological Anatomy at Berlin.

—Iodide of ethyl is recommended by Dr. Bartholow in the treatment of brain syphilis when a prompt action of the iodine is desired.

—Patient—Oh, doctor, can you tell me the character of this tumor on my lip, and remove it for me?

Laconic M. D.—Certainly, I—cancer.

—A Boston physician has recently become the possessor of an opera glass with a good deal of romance attached to it. It was given to the Princess Eugenie by Napoleon III. as a Christmas present. The glasses originally cost 26,000 francs.

—William B. Atkinson, A. M., M. D., the well known Secretary of the American Medical Association, has been elected Professor of Diseases of Children and Sanitary Science in the Faculty of the Medico-Chirurgical College of Philadelphia.

—Dr. Ogle, the Registrar of Statistics in England, has found that the mortality among English physicians for three years, from 1880 to 1882, was 25.53 per thousand, while that of barristers was 20.23, and clergyman 15.98 per thousand.

QUERIES AND REPLIES.

DRY SPONTANEOUS GANGRENE IN CHILD TWO YEARS OLD.

EDS. MED. AND SURG. REPORTER:

I have now in hand a case of dry senile (or so-called) spontaneous gangrene in a child not quite two years old, resulting probably from embolism. I can find no recorded case of such disease at that tender age; I have never seen, nor can I hear of anything of the kind. If any reader of the REPORTER knows of such a case, either personally or otherwise, will he please kindly inform

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

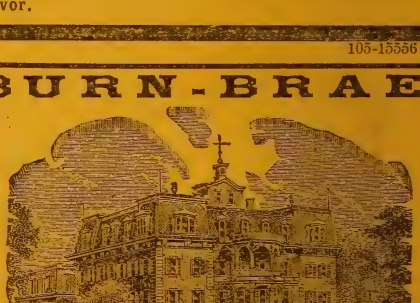
An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease-producing matter.

INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,
36 Platt St., New York.

BURN-BRAE.



This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful Home.

R. A. GIVEN, M. D.,
BURN-BRAE, CLIFTON HEIGHTS, DELAWARE CO., PA.,

Assistant Physician,
J. WILLOUGHBY PHILLIPS, M. D.

THE ADIRONDACKS AS A HEALTH RESORT.

BY GEO. E. SHOEMAKER, M. D.
Of Philadelphia.

Although this region has been visited by health seekers for more than twenty-five years, there is a remarkable lack of medical literature concerning it. No works upon the subject are extant, and in the "Index Medicus" scarcely any references to current literature are to be found. However, an admirable article* by Dr. James J. Levick, of this city, gives some excellent practical suggestions as to particular localities and hotels to be preferred by invalids. Another by Dr. Alfred L. Loomis,† of New York city, gives a clear description of the region, and cites cases relieved or cured by residence there.

The statements of popular guide-books must be received with some caution, because in many instances personal obligation to landlords seems to influence the writers. It is to be regretted that there are no Signal Service reports for this region, as comparisons would be interesting.

The Adirondack region is, as many know, in the north-eastern part of New York State, lying west of Lake Champlain and north of the Mohawk valley. The "Wilderness," as it is called, comprises in area about one-third of the State, and is about 150 miles from north to south, and 100 miles from east to west; its centre lying almost exactly north of Philadelphia, and 400 miles away. A knowledge of the physical features is so necessary to a proper understanding of the peculiarities of climate, that no other excuse is needed for giving a few bare facts here.

It may be briefly described as a rough, wild, very rocky tract of comparatively small general elevation; nearly covered by mountains and hills, which are not in regular ranges, densely wooded throughout, and varied by innumerable lakes and streams, with more or less wet land about them. There are about 8,000 square miles of almost unbroken forest. Most of the mountains, and all of the high ones, are in the central and southern part; most of the lakes and streams in the northern and western. To this lake and hill region, forming a kind of plateau, most of the consumptives go, rather than to the mountains proper, the higher regions being uninhabited. There are absolutely no hotels, boarding houses, or much frequented camping grounds at any considerable elevation. The highest hotel, for instance, is at Lake Placid, only 2,000 feet up. The ordinary altitude of the hotels in the most frequented regions is about 1,500 feet, that of the famous Paul Smith's is 1,623. This seems very small, when we recall the fact that Colorado is part of a high table-land; that almost the whole State is over 4,000 feet above sea level before one begins to ascend mountains at all. Denver is 5,000 feet up; Colorado Springs and Manitou over 6,000. Mount Marcy, the highest peak in the Adirondacks, is a little more than 5,000 feet in elevation; Pike's Peak over 14,000.

There are several hotels in the Cattskills over 1,000 feet higher than any in the Adirondacks, yet the latter far surpass their nearer and more frequented rivals in benefit to the sick.

* Philadelphia Medical Times, Sept., 1881.
† Medical Record, 1879, 385, 489.

In studying the climate, therefore, let us bear in mind the conditions: small comparative elevation, abundance of water in lakes and streams, large extent of region modifying the qualities of the atmosphere, heavy forests, light porous soil.

The temperature exhibits considerable daily range. In summer the nights are cool; 50° F. being about the minimum, with 70° to 95° at midday, according to location, the spots differing more in exposure to wind and sun than in elevation. In winter the cold is great, the mercury often remaining for days below zero in January and February. The cold is constant, however, no thaws occurring before March, and snow lying the whole winter. There is a preponderance of cloudy over the clear days.

Now, in any consideration of this region as a health resort, especially for phthisis cases, we naturally compare it with two others—Florida and Colorado—typical and widely differing from one another. It is, of course, impossible here to go into details of conditions which make both these of great medical interest. Suffice it to say, that Florida, warm, moist, low, attracts from its mildness and equability; there being no stimulus to general activity of function from elevation—the high winter temperature (average 60° October to March) and consequent pleasantness of life out-doors, offsetting the amount of moisture, which is in itself a detriment.

But Florida is only a winter resort; the Adirondacks are claimed to rival Colorado in being fitted for residence throughout the year.

Colorado, on the other hand, cold—very cold in winter—high, dry, variable, depends largely on dryness and expanded air for its value. Besides the general stimulus to activity of organs, and to muscular exercise in Colorado, there is, owing to the dryness, an enormous increase in the amount of moisture exhaled as vapor by the lungs.

As ingeniously calculated by Dr. Charles Denison (*New York Med. Jour.*, September 20, 1884), over six ounces more water a day leave the lungs at Denver than at Jacksonville, other things being equal. It is also reasonably suggested by that author that this vapor furnishes an excellent vehicle for carrying off effete material from wasted and diseased tissue.

Dryness, then, though its influence is exerted in various ways, which need not be here considered, is one of Colorado's strong points. Distance from bodies of water, absence of forests, and situation on the landward side of a great mountain range, go far toward producing this absence of moisture.

These conditions, as we have seen, are not found in the Adirondacks, the whole surface being covered with forests and lakes, to say nothing of the relative nearness of the Atlantic. Consequently we have to deal with a moderately moist climate. Rainfall is above the average of the State, there being many showers, as well as longer storms. The ground on the mountains in summer is always more or less damp, the trees preventing the access of the sun. Fungi, mosses, ferns, plants of the lower orders, thrive in the moist shade. Articles of iron and steel rust under cover, as with us. Yet where the sun's rays fall, evaporation is very rapid, the surface of the porous soil drying quickly after rain. The direct rays of the sun are more powerful than with us; but evaporation from the skin being more rapid, greater physical comfort is possible in summer. In temperature, much of course depends on the spot considered, whether that be sheltered, like "Keene Valley," or in a windy notch, as in the case of the hotel at Edmund's Ponds, one of the coldest places in the region. In August, 1884, for instance, the thermometer one day stood as high at midday in the first-named locality, as was reported in New York city or Boston for the same time, 96° in the shade. This valley, by the way, though much frequented, is a better place for artists and tourists than for invalids.

The region under discussion then is to be classed among the resorts of moderate altitude, such as Asheville, North Carolina, having say 2200 feet of elevation; Walden's Ridge, Eastern Tennessee, 2000 feet; St. Paul, or Brainerd, Minnesota, 1200 feet, etc.

If then we have in the Adirondacks neither great dryness nor elevation, to what are we to attribute the undoubted benefit obtained by some phthisical and other patients there? Several points suggest themselves:

(*a*) Purity of atmosphere from contact with large amount of vegetable surface. Any sources of defilement from crowded animal life or other influence are far removed, which is true also of sea air, of course. Owing to the inclination of the earth's crust and resulting differences of temperature, there must be increased mingling of surface and higher air-currents. These influences are at work on any mountain, but have a much more marked effect on air masses when the region is large, as here, contrasted with

the Cattskills, the White Mountains, or the Pennsylvania ranges. It may be said here that the mountain region of western North Carolina and eastern Tennessee is nearly as large, and in all probability it would be quite as good a resort for invalids but for one point: there is in many places a great lack of food of good quality, well prepared. A more far-sighted class of landlords may change this in time.

(*b*) Soothing, healing qualities of air from the abundance of cone-bearing trees, among others, for instance, spruce, balsam, white pine, yellow pine, hemlock, cedar, and tamarack. The odor of these trees is quite noticeable in the air. Ozone, the mysterious, is abundant. This resinous or balsamic quality, while found at such resorts as Brown's Mills, New Jersey, in its degree and in combination with altitude is distinctive of the Adirondacks.

In addition, there is the constant temptation to out-door llfe, probably the most important factor of all. This, of course, is common to many resorts; and in winter Florida, for instance, undoubtedly presents a more even, as well as a much warmer climate, but with no stimulus to muscular or organic activity. The bracing qualities of Adirondack air would be of priceless advantage to many and many a patient who lives away the months when recovery is possible, and merely temporizes in a climate like that of the south of Europe or Florida, when the stimulation of mountain out-door life, even if more rigorous, would lead to steady improvement.

Another great advantage of the New York Sanitarium is the primitive mode of life of most of its visitors. It is the proper thing in this region to be primitive, live and dress simply, and go to bed early, which is not true of many other resorts. It is true that of late years houses have been built of considerable pretensions, and some of these will hold several hundred guests; but the typical pilgrim lives in a small house, in a tent, shanty, or log cabin in summer; some in handsome cottages. Those who secure most benefit have bade good-bye to furnace heat, fashionable hours, and elaborate hotel cookery. They help themselves, and rough it to a reasonable degree. It is quite possible, as the writer has more than once seen, for a person to miss nearly the whole benefit of the sojourn, first by injudicious choice of locality, then by occupying a small room at a large hotel (and, by the way, sanitary drainage is an unknown quantity to many Adirondack landlords), and in going to a house with too many artificial accommodations. This statement is open to criticism, but it seems to the writer that if it is too cheerful in-doors, the same pampered hot-house life, so common among consumptives, can be adopted in the mountains as at home, with the usual results. This does not apply to the old or the very weak; but there can be no doubt that much of the benefit of all seashore and mountain life comes from the fact that there is less comfortable in-door life than the patient has at home, and he goes out more.

It seems to the writer that one can not be too emphatic in condemning life in the larger mountain hotels, except for the well man. Primitive accommodations, a region out of the dominion of fashion, warm flannels, rough-and-ready clothes, unbounded confidence in out-door air, good plain food, and *good company*, are the essentials. These things may be trite to the physician, but his patients constantly disregard them. The day, sad to say, has gone by when the words "Adirondacks" and "wilderness" were synonymous, and civilization is fast invading the region, so that now more distinct advice is necessary from the physician than simply "Go to the Adirondacks."

Whom shall we send there?

First, the moderately well-to-do, for though hotel rates are generally low (from $8 to $21 per week), the outlay for transportation, guides, and other more or less necessary expenses, is not small.

Subject to a few well known limitations, it may be stated with much earnestness that for the well-defined phthisis case there is but one alternative if *health alone* is considered, and that is to "go West," and stay there, or, after a more or less unsatisfactory battle, to succumb to the disease. In Colorado, for example, he may find a permanent home, and in time home-like surroundings, in a climate where phthisis is practically unknown among the natives. He must stay there, for nothing but a permanent stay, or in some cases a residence of at least two years, can be of much use. To the patient so situated as to make a permanent move possible, the Adirondacks do not offer the same inducements. There are absolutely no business prospects. The region can never be looked upon as a home, except by a few peculiarly constituted and peculiarly situated. In fact, it remains to be proved that a majority of phthisis cases would be sure of immunity for life there. The writer of an enthusiastic article on the Adirondacks in *Harper's Monthly*, four years ago, himself died, it is said, about eighteen

months afterward of phthisis, though, of course, he may have prolonged his life by his going there.

To show that a great factor in the benefit is *change* of climate rather than any altogether inherent qualities of the air, it may be stated that several cases of phthisis among guides and their wives, etc., came under the writer's notice, and several others were within the knowledge of an informant, an intelligent layman. This is no doubt due in some measure to the exceptionally exposed life of some of them, and somewhat to drink and other forms of dissipation. No mention is apparently made of this point by writers.

The great majority cannot, however, go away anywhere for life, and from these we here in Philadelphia can choose out many who will get benefit in the north. To many advanced cases who must cling to home or business here, we have the Adirondacks to prescribe, with generally more chance of temporary benefit than could be obtained at any other eastern mountain resort. Colorado is perhaps too far off, and the trip too expensive. Its elevation is great, and the sudden change might entail disorders which would offset all the benefit of the short stay.

The mistake is often made in this neighborhood of sending such cases to the country around Philadelphia, or to the Jersey coast, perhaps because of its nearness. Now pure air does wonders, but the moisture of the seashore is against most cases of phthisis. Give them mountain air, resinous, not too rare, and the benefit is much increased. Of course, individual conditions must be studied. For instance, it is said that an aged, enfeebled, broken-down phthisis subject is benefited by the sea, while it would do badly in a high mountain region. The same is often true of those who have been of full habit and sanguine temperament, and are liable to hemorrhage. Then for the large class with threatened pulmonary involvement and depressed vitality, needing a tonic climate, near at hand and for a short time, a few weeks or months, we may confidently recommend the Adirondacks, and strongly prefer them to Cresson, Kane, the Cattskills, etc.

The time is coming when physicians will pay more attention to lung expansion and ventilation in the home and in the consulting-room. Mountain air does this for us, and moreover does it constantly and moderately.

Now among the seriously ill, many cases, though needing change, are warned away from Colorado. Such, for instance, according to Dr. Solly, of Denver, an excellent observer of the effects of that climate, are cases of fatty heart and disease of wall or valves with dilatation. To such Colorado is dangerous. Neuralgic heart affections, angina, and the like, do not do well there. Nervous exhaustion, etc., in persons of full habit, likewise acute organic nervous disease, grows rapidly worse. Says Dr. Chas. Denison, in his work on Rocky Mountain Health Resorts: "The more acute and severe the nervous symptoms, the more of an aggravating nature is the effect of elevation." Most of these cases, while debarred from going to Colorado, might benefit enormously in general tone and at the same time be free from new danger in the Adirondacks, where there comes a remarkable exhilaration and feeling of well-being, without great rarefaction of air and consequent increase of heart work.

Again, little hope with considerable danger is offered by Colorado to the acute phthisis case, with extensive deposit, in the stage of softening; also to the chronic cavity case, with a third or half of the lung surface diseased; also where a large cavity easily bleeds.

Now, surely all these may take their summer journey to the Adirondacks with the minimum of danger and the greatest chance of temporary relief. Unfortunately there is too little hope of cure by any means in any climate.

In such cases as are intended for Colorado, but which require building up for the change, and a gradual increase of elevation, the Adirondacks may be prescribed.

Here also is immunity for many asthmatic and hay-fever patients, and a perfect paradise for the tired brain worker who is fond of out-door sport. Dust and dryness do not irritate the throat and nose as in the West, and the catarrh case improves in the tonic air.

The above applies principally to the Adirondacks as a summer health resort. As to its desirability as a winter home, perhaps we have not yet sufficient data for definite conclusions. It was only six years ago that the whole number of phthisis cases wintering there is said to have been fourteen, but several physicians of New York city are quite enthusiastic in its favor. Since the establishment of the Sanitarium by Dr. Trudeau, near the Lower Saranac Lake, much greater advantages are offered to invalids than could possibly be commanded previously.

Of the possibilities for the intense enjoyment of camp and woods life by the well man, nothing has here been said. That is a matter for feeling rather than for expression.

3324 *Woodland Ave., Philadelphia.*

DIAGNOSIS OF RECTAL DISEASES WITH THE AID OF A NEW SELF-RETAINING RECTAL SPECULUM.

BY W. S. WATSON, M. D.,
Of Matteawan, New York.

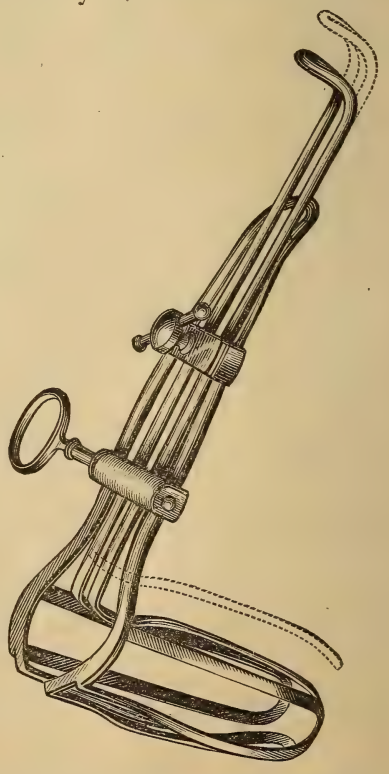
Perhaps there is no class of affections more common than diseased conditions of the rectum. Their pathology, symptomatology, and diagnosis, as a rule, are pretty well understood. There is a class of ailments peculiar to these parts that give rise to a degree of mental suffering, anxiety of mind, and depression of spirits, out of proportion to the real gravity of the local disorder. The real pathological condition may have passed undiscovered for years, which for most part arises from habits of the sufferer that are prejudicial to health, and are most prevalent among the better class of society. Anything which disturbs the normal physiological process may act as an exciting cause. Not unfrequently the first step which leads to an inexpressible amount of suffering, and a disease thought by many to be almost incurable, is a failure to evacuate the bowels, a failure to heed the signal calls of nature. Amid the hurry and flurry of the times, while the masses are living and everything is done on fast time (*i. e.*, railroad time), we need not wonder at the results of such delay or useless hurry. In the present age the demands of society and business are such as to make one feel that to hurry is an imperative duty incumbent upon all, if we would keep pace with our fellow man. We think there is no doubt that the retention of fecal substance in the rectum beyond the calls of nature to evacuate does cause undue distention, irritation, and congestion of the integral parts, which may and not unfrequently does result in hemorrhoids, fissures, abscesses, fistulæ, and irritable ulcers. An accumulation of fecal matter, which in its nature is insoluble, does, by distending the parts and by pressure, retard the return of the blood through the parts, which of necessity must produce congestion of the hemorrhoidal veins, and piles. The long-continued practice of deferring nature's calls is hazardous, and the inevitable results of such continued violation must and will follow, sooner or later. A no less frequent cause of many of the diseases peculiar to the rectum and anus, one not sufficiently dwelt upon by authors, is the hurried effort to defecate. It must, we think, be conceded, that one of the aforementioned violations is about as injurious as the other. What must be the result when a deferred accumulation is forcibly hurried through these parts? Can it be without more or less injury to the parts? The disposition to hurry may be and often is due to the aforementioned causes, hurry of business, etc., but not unfrequently it is due to the repulsiveness and indecent exposure one is subjected to in our water-closet accommodations; especially is this true of many country and city boarding places, and pretty generally is it true of our large manufacturing establishments, where hundreds of the opposite sexes are employed. Water-closets too often are cesspools, filthy beyond description. Not only are these places filthy, but often they offer little or no privacy to the opposite sexes. Under such circumstances, need one wonder at delay? Where is the respectable woman who will not avoid going into such places, or who will not resist the calls to evacuate her bowels as long as possible? and when forced to visit such filthy places, it is natural that the stay be as short as possible. As soon as seated the habit is to bring to bear at once all the power of the diaphragm and abdominal muscles, there being no time to wait until the involuntary and voluntary muscles relax to admit of a free passage. The fecal mass, let it be of what consistency it may, is forced hurriedly against the sphincters, which, of their nature, resist such sudden onslaught, yielding when overwhelmed by the violent force brought to bear, at the expense of the elasticity and tenacity of the parts, with abrasion and laceration of the parts. As a result, an accumulation of days, in some instances weeks, cannot safely and hurriedly be forced through the lower rectum and anus without more or less injury to the parts, which, if often repeated, must result in fissure, irritable ulcers, etc.; while the reverse would be, were sufficient time allotted for dilatation and evacuation to take place by peristalsis alone.

Aside from the causes already assigned, there are others, especially in women. It is, we believe, conceded that diseases of the rectum and anus are of more frequent occurrence with them than in the male, due to the many altered conditions to which the uterus is subject, viz., enlargements, displacements, deranging the circulation and mechanically, or otherwise, producing various lesions of the parts. The influence of the enlarged uterus of pregnancy is a frequent source of disorders of the rectum. A uterine origin for diseases of the rectum has not been generally suspected nor sufficiently recognized, and to this fact many failures in the treatment may be ascribed.

Treating a woman affected with constipation, piles, and intestinal disorders of a secondary nature, by measures directed to the lesion within the rectum as a primary disease, the patient will receive little or no benefit other than palliative. A due recognition of the intimate relation between these parts must be recognized if we would be successful in the management of this class of ailments in women.

While it is all-essential to know of the various causes which lead to diseases of the parts under consideration, it is no less essential to be able to make a positive diagnosis of them.

An accurate diagnosis, says the late Dr. Van Buren, is an unerring test of true scholarship; and of all the qualities that go to make a truly great physician, it is to be an accurate diagnostician, for it is this alone that insures success and consequent reputation. The saying of Dr. Van Buren may well be applied to the class of ailments under consideration. A careless or imperfect diagnosis of these ailments is by far too common, and has brought the treatment of rectal diseases into disrepute. To be sure, they are by nature hidden away, as it were, in the recesses of our bodies, and modesty is averse to their disclosure or exposure. Were the profession in possession of efficient means for their disclosure, there would be no excuse for them; but it is lamentably true that all devices heretofore in use have been so unsatisfactory that we have felt a little timid in our demands of patients suffering with this class of ailments to submit to an exploratory examination or ocular inspection, knowing the devices to be ill adapted to the purpose designed, and that little or nothing can be learned by their use in consequence of the narrowness of their blades or from a want of more blades. Bivalve speculums give only a lateral dilatation, consequently there is a bulging in of the mucous folds of the parts antero-posteriorly, which obstruct the view to such a degree that a correct diagnosis cannot be made, while if the real pathological condition was known, very few diseases are more amenable to treatment when properly appreciated, or give better results to the surgeon, than do rectal diseases; while the reverse is the case if treated on the expectant plan, by blindly prescribing ointments, laxative mixtures, etc., for supposed conditions. Few if any diseases will prove more obstinate or bring more reproach upon the skill of the physician, than tampering with the parts under consideration without a full knowledge of the real pathological conditions, which cannot be known without a careful ocular inspection of the parts, which inspection can only be had with the aid of a speculum that will positively hold apart the loose folds of these parts and give an equal distention in all directions, at the same time affording plenty of reflected light within the parts, covering up but little space at any one point of contact. Knowing such a device to be essential to the successful understanding of the real condition, we have had made a rectal speculum that we believe comes up to all the requirements for examining and treating about all of the diseases peculiar to the rectum and anus. The device is so constructed that it is easy to introduce. It is are made of steel wire flattened in part and so bent as to form three and four fingers or blades, with a contraction in their formation suited to the contractile action of the sphincter muscle that holds them in place, requiring no assistant for the purpose. Dilatation laterally is by means of a transverse screw operating across the handle. Dilatation antero-posteriorly is brought about by a movement of the retractor blade, as shown in the cut by dotted lines.



The retractor part is a most excellent device in the combination; with the aid of it,

folds can be made as tense as necessary to straighten out any bulges that would otherwise obstruct the view. The retractor part materially aids in rendering the speculum self-retaining, a highly commendable feature to the physician in private practice.

It, of course, would be impossible in a short medical journal article to touch on all the details of the many causes that are productive of the various lesions of the rectum and anus; our intention was to touch on a few only of the most common among them. The cause and effect as herein set forth may seem to some to be a trivial one, but the reverse is the case. Extended observation and careful study of this class of ailments has led us to consider them worthy of more thought and attention from the profession than has been allotted them. Our purpose in bringing to the notice of the profession the claims herein as to cause and effect, and in calling their attention to our device for diagnosis and treatment of rectal diseases and diseases of the anus, is that full justice be done our patients, and the profession relieved of the annoyance heretofore attending the use of other unsatisfactory devices for the purpose. We feel sure that we are warranted in saying that the treatment is a practical one, and of great value to the medical profession, for there is a wide field for its usefulness. With the aid of this device for ocular inspection, a positive diagnosis can be arrived at, and the real pathological condition known, and therefore successfully treated.

DISORDERS OF PERSPIRATION.

BY J. B. JOHNSON, M. D.,
Of Washington, D. C.

The aggregated length of the perspiratory tubing is about eight miles; and these sudoriparous glands consist of a tube convoluted into a glomerulus at its inner or deeper extremity, but its free ends follow a somewhat flexuous course outwardly, and after passing through the epidermis, finally open upon the external surface of the body. Their function is to secrete the sweat; and the average amount of perspiration which is thrown off by them during the warmer and colder months of the year, nearly equals the amount of urine excreted by the kidneys. Therefore the action of the perspiratory tubes, and of the kidneys, is reversed in hot and cold weather. The perspiration will be two times more in July than in February, and the urine will be twice as much in February as in July. When the secreting organs of the body are in a diseased condition, they usually present one or the other of three conditions, viz: Augmentation, diminution, or alteration of secretion. The sudoriparous system is not an exception to this rule; and when the perspiratory function is interfered with, the interference must consist in one of these three varieties. Dermatologists have given to these three disorders of perspiration, distinctive names. They have named augmentation of perspiration, *idrosis*, *ephidrosis*, and *sudatoria;* and they divide this into idrosis simplex and idrosis maligna. A diminution of the secretion of perspiration is called *anidrosis*, and an alteration of the secreted perspiration is known by the term osmidrosis. Anidrosis refers to that condition of the perspiratory fluid which is manifested during the continuance of febrile diseases, and osmidrosis relates to the character of the odor which the perspiration gives out during the existence of certain diseases of the body. These two varieties of morbid perspiration are evidently to be more respected as symptoms than regarded as diseases, for they are never conspicuous unless in the presence of some derangement of the internal organs of the body.

IDROSIS SIMPLEX.

This disorder of the function of perspiration is the most common, and is divided into subacute and chronic. An attack of subacute idrosis usually terminates in a week or two, and is more often partial in its appearance than general; and in two or three days after its existence a crop of vesicles show themselves about the neck, trunk, and abdomen, and usually pass to the armpits and inner parts of the thighs. This form is attended not only with feverishness, but with disorder of the alimentary canal. The only treatment this form requires is a correction of any disorder of the stomach and bowels and the prevention of its sudden arrest, lest its untimely disappearance be followed by a congestion of some of the internal viscera. This variety is also known by the name *sudatoria miliaris*. Chronic idrosis differs from the subacute in the particular feature that it is not apt to be accompanied by either constitutional disturbance or the appearance of miliary vesicles, but is prone to be very chronic, and in some instances will and does thus continue, independent of any other affection, in a general form for five or ten years; but its rule is to be partial, and confine itself to either one side or the other of the body, generally to the hands and feet. I was once consulted by a female patient,

who informed me that she only sweated on one side—the left side—and she had not sweated on the right side for years. The scalp, perineum, groin, and axilla are attacked by it; and in consequence of the acid character and disagreeable odor of the perspiration which belongs to idrosis, it becomes a source of great annoyance to the patient. The perspiration is sometimes so profuse as to keep the inside skin of the hands and the soles of the feet in a softened, corrugated condition—like that which the skin will present after being kept in warm water for a long time. The sweat in extraordinary cases of idrosis is blue, green, yellow, and sometimes black or red; but this is a rare abnormal condition, and has received the names hæmidrosis and chromidrosis. Idrosis maligna is the name which was given to the sweating sickness of the sixteenth century.

THE TREATMENT.

There is no doubt then, in many cases of simple idrosis, that the disease owes its origin to a chronic inflammation of the perspiratory tubes themselves, and is therefore a purely local disease; but in other cases it is evidently symptomatic of some derangement of the general system. Notwithstanding this, it is usually an obstinate disease, and requires tedious treatment for its cure. The first duty in the treatment is to regulate the secretions of the alimentary canal. For this purpose, a dose of blue mass should be given, followed by the following mixture:

℞. Sodii sulphat., ℥j.
Acid. sulphuric dilut., ♏iss.
Aquæ Carui, ℥viij.
Ext. gentian. fld., ♏j.
Fowler's solution, ♏j.
M. Sig.—Shake well. Dose, a tablespoonful before each meal.

This should be continued until the arsenic shows its effect in producing puffiness of the eyelids and slight swelling of the face. At the same time, the following will be found very useful:

℞. Resorcin, ℥iss.
Tinct. aconit. rad., gtts. xxxij.
Liquor ammoniæ acet., ℥ij.
Syrup aurant. cort.,
Aquæ distil., āā ℥j.
M. Sig.—Shake well. Dose, a teaspoonful every three hours. The dose of tinct. aconite should be increased gradually to fifteen drops a day.

It is reported that extract of aconite cured a case of chronic general ephidrosis which had lasted for six years independently of any other affection, and which, after resisting various remedies, did yield to the power of this drug given in the beginning, in doses of one-half grain three times a day, and gradually increased until sixteen grains a day were given, and so continued until the disease was cured. In cases needing a tonic treatment, this formula will probably be found to be very serviceable:

℞. Tinct. ferri perchlor., ♏ij.
Liquor strychniæ, gtt. xxxvj.
Liquor ergotæ, ♏ss.
Syrup, simpl.,
Aquæ distil., āā ♏iij.
M. Sig.—Shake well. Dose, a tablespoonful three times a day.

Local treatment is not to be neglected in cases of idrosis of the hands and feet. As an application to the hands, I have found the following most effectual:

℞. Pure Carolina pine tar,
Alcohol, āā ♏j. M.
Sig.—Shake well and apply with a camel's-hair brush to the hands twice a day, and keep them protected by cotton gloves.

Should this fail, a mixture of—

℞. Acid. tannici, grs. xxx.
Glycerinæ, ♏j. M.
Sig.—Shake well and apply two or three times a day to the hands or feet.

Should this also fail, chloride of lime and tannic acid may be tried:

℞. Calcis chlorin., ♏iij.
Aquæ distillat., Oj.
Solue et cola, et adde,
Acid. tannici, ♏iij. M.
Sig.—Apply to the hands or feet two or three times a day.

The following will be found a good application to the hands and feet:

℞. Richardson's styptic col., ♏j.
Carbolic acid, grs. xx. M.
Sig.—Apply three or four times a week.

A strong solution of alum may be tried, and for the feet, a strong brine foot-bath ought to be tried every night at bedtime. This course, or whatever course of treatment is adopted, must be continued patiently, and with perseverance.

NOTE.—The above essay was suggested by "Queries and Replies" in REPORTER of June 5.

—Prof. Albert Robin, in the *Gazette Medicale de Paris*, from a long discussion and study of the subject, concludes that in cases of obesity, if there be a small excretion of urea, fluids should be freely administered; but if there be an excess of urea secretion, fluids are to be avoided.

Medical Societies.

BALTIMORE GYNÆCOLOGICAL AND OBSTETRICAL SOCIETY.

Regular meeting held May 11, 1886. The President, Dr. Geo. W. Miltenberger, in the chair. Dr. W. E. Moseley, Secretary.

Dr. Robt. T. Wilson read a paper entitled

Hysterectomy for Removal of a Fibro-Cystic Tumor.

It will be remembered that at the meeting of the "Obstetrical and Gynæcological Society of Baltimore City," held January 12, I exhibited a specimen of a very large fibro-cystic tumor, which I removed the day before from a woman at the Union Protestant Infirmary. I then promised to give you a history of the case and of the operation at a future meeting, and I am here this evening to fulfil that promise. I also desire to show to you, by a photograph, which I made myself, the appearance of the abdomen before the operation.

In January, of this year, Mrs. J. M. came under my care at the Union Protestant Infirmary. Upon questioning her, I found that she was forty years of age, and born in this State. She first menstruated at eleven years of age, and it has come on regularly every four weeks ever since, each period lasting four to five days, but not too free, and having no pain to speak of. Five years ago she weighed one hundred and sixty-three pounds; and three years ago she noticed that she was losing flesh all over her body but in the abdomen, where she felt weighty and had a heaviness. The abdomen has been increasing in size for the past two years. In June last she measured around the abdomen thirty-eight inches, and in July forty inches.

During the past two years she has suffered with dragging and bearing-down feelings in the back, and pains frequently shooting through back and abdomen. At times she would pass a very small quantity of urine, Bowels generally regular. Two years ago, and also last summer, she laced tightly. She did so because she was told to do it, and not that she felt better from it, for she noticed no change in her feelings. Only from worry would she have headaches. She has been married twenty years, but her face showed the lines of care well depicted upon it; the "facies ovariana" was observed. She was confident that each day she was getting larger in the abdomen, and her strength daily lessening. She said she must be helped, and if there was a chance for her to be relieved of the tumor, she would like to have it removed, as she felt that she could not last longer as she was, her sufferings having increased the past four or five months.

Upon examining the abdomen, I found dullness on percussion over the whole abdomen; uncertain and indistinct resonance on percussion in the left lumbar region; clearness in the right; below the umbilicus, and to the left side, upon palpation, fluctuation was distinctly felt. By digital examination per vaginam pelvis was clear, and the uterus measured three inches in length. From this examination and the size of the tumor being so great, and its growth within the past few months being so rapid, surgical interference became imperative. So on the 11th of January, the patient being etherized by Nathan R. Gorter, M. D., I made an incision four inches in length in the median line, beginning two inches above the pubes. As soon as the cavity was opened there was a great discharge of bloody serum. Pressure upon the tumor by the finger also gave the sensation of fluid within.

The trocar (Wells') was pushed into the tumor, but only a little blood escaped. The incision was enlarged to six inches, and further exploration made with the hand, when it was found to be a tumor in which the uterus and ovaries were involved.

The incision was carried above the umbilicus, the length of incision then being eleven inches.

The tumor grew from the whole back part and side of the uterus; it was attached to the left iliac fossa and left brim of pelvis, and left side of the abdominal walls back to spinal column. It was attached also to the omentum, intestines, and bladder.

The omentum could be peeled off, but its vessels were very large, so that in many places it had to be ligated and cut from the tumor in sections.

The intestines were situated behind and above the tumor.

The tumor at its lower part projected prominently forward over the symphysis pubis, and evidently contained fluid at this point, so that I was in doubt whether it was a cyst or the bladder distended with urine.

This point was cleared up by passing a sound into the bladder, which accurately outlined the extent of its attachments to the tumor; and with the sound as a guide I punctured the cyst, and evacuated from this part of the tumor a pint of transparent,

straw-colored fluid, which spontaneously coagulated, and the sac only in part collapsed. With great difficulty the bladder was separated from the tumor, but numerous bleeding points had to be ligated before the oozing from its surface was controlled. By hard pulling and pushing, the huge mass was slowly drawn forwards as far as its connections to the back and left side of pelvis would permit. The intestines were carefully peeled off from the tumor. The attachments were so dense and vascular that they could only be separated by gathering them up in sections, applying double ligatures, and cutting between, so that when the tumor was freed from its pelvic and abdominal adhesions there were thirty-three ligatures left in the abdominal cavity. During the operation she lost very little blood. As all vessels were clamped or ligated as soon as the tumor was freed, I placed Keith's hysterectomy clamp around the uterus, just above the vaginal junction, and cut away the mass. Three drainage-tubes were introduced: one to the bottom of the pelvis, and the others at different points in the abdominal cavity. The reason for introducing so many drainage-tubes was on account of the great amount of bloody serum that poured out from the surfaces of the extensive adhesions.

The stump was closely trimmed off, and the portions above the clamp touched with liq. ferri sub.-sulph. The wound was closed with nine silver wire sutures, and iodoform freely sprinkled around the stump, the usual dressing applied, and the patient placed in bed.

Just before the operation, she was given, by the mouth, a tablespoonful and a half of whisky in some water. The heart's action not being good, ether was the anæsthetic given. Her pulse, under the ether, in the beginning was 100, and very feeble. And during the operation it was necessary to give her repeated hypodermics of whisky, and she received by this means ʒxvi. (m. 960). A syringe was used which holds m. 75.

During the operation her body was kept warm by hot bottles and blankets. The operation lasted one hour and twenty-five minutes. She never reacted, and died in twenty-six hours from shock. Much bloody serum flowed from the drainage tubes, and the abdominal cavity was washed out several times with bichloride of mercury, sol. $\frac{1}{2000}$, the fluid being thrown in through one tube and flowing out freely through the others.

Previous to operating, the urine was chemically examined, and was found to be acid in reaction; color, deep amber hue; specific gravity 1020; slight amount of albumen (heat and nitric acid tests); measurement around the body forty-six inches.

The tumor weighed thirty-one pounds after much bloody serum had drained away from it. The tumor was placed in the hands of Dr. Wm. T. Councilman, of the Johns Hopkins University, for examination, and I herewith read you his report.

"Johns Hopkins Hospital,
"Baltimore, *January* 27, 1886.

"Dr. Robert T. Wilson—*Dear Sir:* The following is the result of my examination of the specimen you sent me. The smaller mass, which presented the appearance of a bifid uterus, was found to be a portion of the uterine canal with a large myoma on either side. These were the size of small oranges, and one was degenerated in the centre. The large mass was smooth on the surface, and gave unmistakable fluctuation. Attached to the surface was a fallopian tube and a corner of the uterus. The tube was elongated and dilated.

"On section the tumor presented a fibrous appearance, was very œdematous, and contained numerous cysts of various sizes. These cysts did not communicate with one another, and were filled with a clear straw-colored fluid. Some of them contained attached to their walls large masses of fibrin. At various points in the œdematous tissue of the tumor were small round nodular masses, which projected above the cut surface. The fluid contained in the cysts was slightly alkaline, gave on boiling an abundant precipitate of albumen, and had a specific gravity of 1017. Microscopic examination of the tumor showed that it was a typical fibro-cystic tumor. The small hard nodules showed a myomatous structure very little altered. In other portions there was very extensive hyaline and mucoid degeneration. The tumor was covered by peritoneum, which could be stripped off. Very truly,

"W. T. Councilman."

When undertaking the operation, I was in doubt as to the exact character of the tumor, whether it was a fibro-cystic tumor of the uterus, or a compound multilocular tumor of the ovary. It was so large, and growing so rapidly, and the sufferings of the woman so great that she demanded relief, and desired to undergo any operation which would give her a reasonable chance for life, and hence I made every preparation, either for an ovariotomy or a hysterectomy.

Dr. Thomas Opie said he would like to ask Dr. Wilson whether he had ever had

signs of poisoning or local irritation from the use of so strong a solution of bichloride of mercury as $\frac{1}{2000}$. Judging from his experience with corrosive sublimate in obstetrical practice, one part in two thousand was much too strong. In one of his cases it had caused a severe metritis. He called attention to statements recently published that biniodide had proved to be quite as effective as the bichloride, and can be safely used as a germicide, in the strength of $\frac{1}{4000}$.

Dr. W. E. Moseley, in regard to washing out the abdominal cavity with so strong a solution as that advocated by Dr. Wilson would merely repeat the remarks he made at a previous meeting. He considered that in placing such a solution in contact with so extensive an absorbing surface as that presented by the peritoneum and abdominal contents, there was great danger of general poisoning and also of local irritation. He believed that all the requirements would be met by the free use of freshly boiled water used directly from the vessels in which it was boiled.

Dr. W. P. Chunn asked how soon the fluid removed from the larger or main tumor coagulated, and what its appearance was.

Dr. R. T. Wilson answered that, as he had stated in his paper, the fluid was straw-colored, and coagulated within two hours.

Dr. H. P. C. Wilson stated that he had repeatedly used the bichloride solution in the manner and strength advocated in the paper read, and had never seen any bad effects follow; Dr. Thornton and other English surgeons use the same solution freely.

Dr. T. A. Ashby remarked that Dr. Hofmeier, of Berlin, had reported in the *American Journal of Obstetrics*, as far back as May, 1884, several cases of poisoning from the use of weak solutions of corrosive sublimate in the puerperium. Bodlehner has observed that sublimate solutions of $\frac{1}{4000}$ for vaginal injections will produce some irritability, and in view of this fact, he thought soltions of $\frac{1}{10000}$ were sufficiently active for vaginal injections. What is true in this respect of vaginal injections is applicable to the use of the bichloride solution in abdominal surgery. The peritoneal membrane is a far better absorbent surface than the vaginal or uterine mucosa. When it is considered that the strength of the sublimate solution of $\frac{1}{2000}$ is equal to three and a half grains of the bichloride of mercury to the pint of water, and that frequently the abdominal cavity is irrigated with from one quart to one gallon of this antiseptic wash, an idea may be had of the danger of absorption from the ten, fifteen, or twenty grains of bichloride in this manner used. In abdominal surgery the strength of the bichloride solution should be feeble. Dr. Ashby thought a solution of $\frac{1}{10000}$ amply sufficient when employed in this manner, and that the stronger solutions were dangerous in proportion to their strength.

Dr. A. H. Erich thoroughly agreed with the view expressed that for douching the abdominal cavity freshly boiled water would meet all the requirements. If there were any suspicious points, they could be touched with a sponge wet in the bichloride solution. He had nearly lost a patient from carbolic acid poisoning. and it had put him on his guard against the too free use of corrosive sublimate. He thought a great deal depended upon the condition of the peritoneum, and that we ought always to be on our guard lest free absorption and poisoning should take place.

Dr. T. A. Ashby read the following paper:

The Influence of Pregnancy and Parturition upon Organic Cardiac Disease.

During gestation the heart is called upon to perform increased duty in maintaining the circulation of an increased volume of blood of an increased arterial tension, and in distributing the blood-supply into new and rapidly developing vessels and tissues. As a result of this assumption of greater exercise and frequency of ventricular contraction, hypertrophy of the left ventricle is constantly found in the pregnant woman. The heart is prepared in a physiological way for the extra duty exacted of it, and it continues to perform this duty until the influence of pregnancy is withdrawn. Of the various modifications imposed upon the female organism by pregnancy, none is more astonishing than the functional activity of the heart under the influence of gestation and parturition. The test of cardiac soundness seems to be thoroughly tried. If any defect exists in the circulatory apparatus, it is most likely to be made manifest under the trial to which it is subjected. Assuming that a healthy circulatory system is required to meet the extra strain and ordeal of pregnancy and labor, we should expect to find organic heart disease unfavorably influenced by these conditions. and especially by the latter function, as the disturbances of the heart's action are more pronounced under the ordeal of severe exercise than at any other time. Under the influence of uterine contraction the large volume of blood distributed to the uterus is suddenly thrown back into the general cir-

culation, and must be provided for by vaso-motor influences. Alternate contraction and relaxation take place with great suddenness, and unless the compensatory laws which preside over the entire circulatory system work with promptness and energy, disturbances of a more or less serious character are unavoidable. The equilibrium of the circulation must be maintained by the promptness with which the heart and blood-vessels —arteries, veins, and capillaries —adjust their action to the rapid change of conditions which occurs in labor. Aside from the profound moral impression which labor makes upon the majority of parturient women, the physical exertion and the sudden disturbances of the blood-supply to the uterus call for the expenditure of great energy and force upon the part of the heart and its vessels, a force which is not easily measured by any other standard of exercise to which woman is subjected.

When the heart is prevented by disease from adjusting itself to the conditions mentioned, variable influences will be experienced. The extent of these influences must depend upon the character of the organic changes, or upon the character of the labor. It is well known that patients suffering from serious organic disease pass through the ordeal of labor triumphantly. The compensatory action of the heart, if disturbed at all, is fortunately adjusted, and delivery takes place, it may be, with no alarming symptoms. If such be the happy termination of labor in even the majority of cases suffering from organic cardiac disease, it is not the invariable rule. The late Dr. Angus Macdonald some years ago collected twenty-eight cases of pregnancy complicated with cardiac disease, of which seventeen died during labor. Macdonald's observations led him to formulate the opinion that the evils resulting from pregnancy in connection with cardiac disease are due to two causes: first, destruction of the equilibrium of the circulation which has been established by compensatory arrangements; secondly, the occurrence of fresh inflammatory lesions upon the valves of the heart already diseased.

Spiegelberg attributed the grave symptoms of mitral disease presenting themselves during labor, or soon after confinement, to excessive distention of the right heart with blood forced from the contracted uterus. Fritsh opposed this idea, and attributed the morbid phenomena of mitral disease to the accumulation of blood in the abdominal vessels recently released from the pressure of the gravid uterus, and to the cardiac paralysis resulting from an insufficient blood supply and consequent defective nutrition of the heart.

The influence of pregnancy and labor upon the circulatory apparatus may be viewed from three standpoints:

1. The influence exerted upon the heart and blood-vessels affected with organic disease prior to pregnancy.

2. The influence exerted upon the heart's valves and upon the heart's action during uterine contraction.

3. The permanent damage which the heart sustains from the influence of pregnancy and labor.

It is proposed to consider these conditions in the briefest manner, as the discussion of this subject cannot be elucidated by any important clinical facts within our possession. We must draw surmises rather than offer data to establish conclusions.

1. The influence of pregnancy and labor upon organic cardiac disease may be considered as unfavorable. A heart already crippled by disease is poorly prepared for the increased exercise and disturbing influences of labor. The heart is called upon to put forth unusual effort during uterine contraction in consequence of the irregularity of the blood-supply to the uterus and pelvic organs. The entire circulatory apparatus is required to functionate under extraordinary conditions, and any weak point in the construction of this circulatory apparatus is exposed to imminent danger. If the heart itself is at fault, the damage will be inflicted upon it, resulting in impaired or suspended action; or if the defect reside in artery, vein, or capillary, rupture of one of these vessels may be the result, with circumscribed or general extravasation of blood into surrounding tissues; cerebral hemorrhage, pelvic hæmatocele, or effusions of blood into cellular tissue are not unknown results of the influence of labor upon the vascular system.

2. The influence exerted upon the valves of the heart and upon the action of the heart during uterine contraction is extremely variable. As the general rule the cardiac valves are capable of sustaining the increased tension thrown on them by uterine contraction. The right heart may, however, become over-distended and the phenomena of mitral disease may manifest themselves. We have elsewhere stated the opposing views of Spiegelberg and Fritsh in regard to this question. It seems to us that there is truth in both of these theories, and that over-distention or insufficiency of the blood-supply to the heart may equally well account for the

phenomena of cardiac irregularity or paralysis. The heart's action may undoubtedly become tumultuous, labored, or disturbed by the diminution, or by the increased pressure of the blood-supply. The exceedingly rapid action of the heart following violent post-partum hemorrhage is an explanation of the effect of diminished blood-supply to the cavities of the heart. It can make but little difference whether the blood-supply is simply diverted and thrown into the pelvic vessels, as suggested by Fritsh, or whether it is lost by escape from the uterine sinuses; the temporary effect upon the heart must prove the same. Over-pressure of the blood-column upon the heart's valves might be sufficient under extreme conditions of arterial tension to induce temporary or even permanent insufficiency, or a rupture sufficient to destroy cardiac action at once.

3. Permanent damage to the heart and vascular system is not an impossible result of the influence of pregnancy and labor. The physiological hypertrophy of the left ventricle is undoubtedly compensatory, and, so far as it goes, actually improves the circulation; but whilst this may be necessary to maintain an increased blood-pressure and arterial tension under ordinary circumstances, it is probable that under certain conditions permanent enlargement and even dilatation of the heart may persist after gestation. As a result of the extra strain of pregnancy, valvular inflammation may supervene and permanently impair these structures by plastic deposits or by ulceration. During labor the pressure exerted upon the valves may likewise result in permanent incompetency. There may therefore persist a stenosis or incompetency of either the mitral or aortic valves.

There is no clinical evidence, however, in our possession to establish these conclusions, but they seem tenable on purely anatomical and pathological grounds.

Where organic lesions exist prior to pregnancy the case is different. The influence of pregnancy and labor can scarcely do otherwise than promote further pathological changes, even though the ordeal of labor is successfully passed through.

Macdonald takes an unfavorable view of the prognosis of labor associated with cardiac disease. His statistics show a mortality of sixty per cent. He was so impressed with this idea that he considers marriage contra-indicated when cardiac disease is known to exist. This suggestion, if acted upon by those who have knowledge of the existence of cardiac disease, would, no doubt, do away with not a few of the serious complications of child-bearing.

The dangers of wedlock should at least be explained to such persons by the family physician, whose advice is often sought, if not always accepted by his patients. Should cardiac trouble be recognized after pregnancy has been established, the existence of a diseased heart should arouse the obstetrician's interest and anxiety. The ordeal of labor is not to be considered with levity if the history of the following case is in keeping with the usual behavior of such cases.

"During the latter half of the month of December, 1880, Mrs. M. called at my office and engaged me to attend her in her approaching confinement. She was between six and seven months advanced in her second pregnancy. The appearance of my patient made an unfavorable impression upon me, and I made close inquiry into her condition. She was tall, slender, and anæmic, and was below par in general health. She had suffered with distressing nausea, weakness, and anxiety during gestation, and expressed serious forebodings of her approaching confinement. I found, upon physical examination, that both the mitral and aortic valves of her heart were defective. She had a decided mitral regurgitant and an aortic obstructive murmur. The heart was hypertrophied. It was performing its duty with regularity and force. Pulse good; no œdema or dropsy. Her condition was one of general debility, anæmia, and nervous excitement. I saw this patient several times during the next few weeks, and gave her such instructions in regard to her confinement as were deemed advisable in the way of prophylaxis.

"On the night of February 28, 1881, I was hurriedly called in to attend this patient in labor. Being absent from my office at the time, it was over a half hour before the message reached me. I hastened to the patient's bedside, and upon entering her room found her in the most alarmed and excited condition. She was tossing herself from one side of her bed to the other, throwing her arms about in confusion, and crying, 'Help!' 'I am dying!' 'Do save me!' and other wild and terrifying exclamations. I soon restored a degreee of quietude, and made an examination. The child had been delivered fifteen or twenty minutes prior to my arrival, but the placenta had not come away. Introducing my finger into the vagina, I found the placenta firmly attached to the upper left segment of the uterus. I removed it with some difficulty. The uterus at once contracted firmly and hemorrhage

ceased. Ergot and brandy had been given hypodermically. The amount of blood lost prior to my arrival was considerable. I estimated it at between 16 and 20 ounces. There was no bleeding after the detachment of the placenta, and, as far as I could determine, the amount of blood lost was not sufficient to account for the great depression and alarming condition of my patient. The firm contraction of the uterus and suspension of the flow of blood failed to exercise any beneficial influence upon the patient. Her nervous, excited, and alarmed frenzy broke out with renewed violence, and in spite of every injunction she would not be quieted nor comforted. Her circulation may be described as horrible. The heart was beating with great violence, irregularity, and excitement. Its action was thumping and tumultuous. It vainly and vigorously attempted to expel the flow of blood emptied into its cavities, but with such poor success that pulmonary congestion was soon established, respiration was hurried and embarrassed, and dyspnœa was becoming alarming. The circulation at the wrist, and in the lower extremities, was barely perceptible, though the heart-beat was heard some inches from the thorax. The action of the heart continued this irregular, tumultuous beat until about 1 o'clock a. m., when suddenly its action suspended, and my patient died with the exclamation on her lips, 'I am dead!'

"The closing scene of this drama is better remembered than described. It suggested the total inability of human skill to establish a normal condition when organic disease has entered in to complicate a physiological function.

"Reviewing the symptoms observed in this case, I was convinced then, as I am at the present day, that the post-partum hemorrhage was not sufficient in itself to have accounted for the death of my patient. I doubt not the hemorrhage was an important factor in the disturbance of the heart's action, but had this organ been in a condition to perform its physiological function, the loss of blood sustained would have imposed no severe hardship upon this patient. Organic disease had so impaired the working power of the heart, that the moment extra effort was required of it to preserve the equilibrium of the circulation, it broke down in the performance of its duty and failed to adjust itself to the requirements of the situation."

Dr. Erich said that some six or seven years ago he was called in consultation to see a woman who was some four months pregnant and had some form of organic heart disease, the exact character of which he did not remember. The question to be decided was whether or not abortion should be induced. He advised allowing the woman to go on to full term, and was afterwards called upon to attend her in her labor. He used morphia in quantities just sufficient to control the nervous system, and when labor pains fairly set in, used chloroform systematically and delivered very slowly by forceps, simply helping each contraction. The result was perfectly natural recovery. He thought that if Dr. Ashby had been able to be with his patient from the first the result would have been very different, as he believed that the death was due rather to the nervous disturbance than to the hemorrhage.

Dr. W. T. Howard said that he had listened with great pleasure to the reading of Dr. Ashby's lucid and interesting paper. He thought, however, that the statistics collected by Dr. Macdonald, giving a mortality of seventeen out of twenty-eight cases, or sixty per cent., from the deleterious effects of pregnancy and parturition on chronic organic disease of the heart, were much higher than is usually seen in private practice. He had attended many ladies in private practice during their accouchement who were suffering from severe cardiac lesions, and he did not remember a single death. Dr. H. felt well assured that he would be sustained in this statement by our President, whose experience in obstetrics, as we all know, is immense. He would ask if such had not been the result of Dr. Miltenberger's experience—if such cases did not usually pass safely through the pangs and perils of labor with due care and attention?

Dr. H. said that the mortality in the cases under discussion would doubtless vary with the nature and extent of cardiac lesions. It is now well known that there is a physiological hypertrophy of the heart during pregnancy, to sustain the burden imposed by the demands of a quickened circulation and the complicated exigencies of the constantly growing uterus. And some cardiac lesions are much more dangerous than others. Thus mitral stenosis is especially apt to occur during the period when child-bearing is most active, rarely occurring after fifty years of age, and it is at least twice as frequent in females as in males. And as stenosis of the mitral orifice is generally accompanied by mitral insufficiency, this complicated condition is particularly dangerous during pregnancy and parturition. Aortic stenosis, also, is generally associated with aortic insuffi-

ciency, more or less, and is always accompanied by hypertrophy of the left ventricle. So long as the hypertrophy is sufficient to compensate for the regurgitation, grave symptoms seldom supervene. Dr. H. well remembered attending a lady some fifteen years ago, aged twenty-five years, who had well-marked aortic stenosis, and also slight insufficiency. The labor was severe and protracted, and finally the vital forces began to flag, and orthopnœa was distressing. But by propping up the shoulders and delivering with the forceps, all went well. This lady is now living, and enjoys a fair proportion of health. When the mitral regurgitation is the predominant lesion, the patient may long remain free from distressing symptoms. The left auricle first feels the strain from pressure of the two blood currents during diastole, one from the left ventricle and the other from the lungs, and begins to dilate and hypertrophy. This leads to compensation hypertrophy of the right ventricle, which overcomes pulmonary hyperæmia and its inevitable train of dreadful sufferings. And as long as hypertrophy of the right ventricle is sufficient to counterbalance the effects of regurgitation, serious symptoms do not result. Dr. H. remembered the case of an eminent literary gentleman from Virginia who consulted him in April, 1861, and who had a loud mitral regurgitant murmur. He is now living, and ably editing a newspaper, and occasionally writing excellent poetry.

Illustrations of Exceptional Symptoms and Examples of Rare Forms of Disease.

Mr. Jonathan Hutchinson thus writes in the *Brit. Med. Jour.*:

Recurring Attacks of Chilliness Followed by Slight Erysipelas of Face: Xanthelasma of Eyelids.

Mrs. B.'s account of her symptoms was very interesting. She said that she had, for three years, been liable to periods of chilliness, during which she could not keep warm. Nothing warmed her; neither exercise nor fire-heat; the nearest approach to warmth being obtained in bed. After two or three days, the attack would end by a blush of redness appearing across the forehead. When this came, the chilliness always ceased. During these attacks, she does not usually feel ill, but takes her food almost as usual. Recently, that is, during the last six months, the attacks, which have recurred almost monthly, have been attended by swelling of the eyelids. The lids, when I saw Mrs. B., were still somewhat swollen, the lower ones especially, and the condition of solid œdema of the lids was clearly threatened. Her ears also had of late become swollen and red during the attacks. Thus it seems probable that the attacks of chilliness were really a modified form of rigor preceding slight attacks of recurrent erysipelas. It is remarkable that they should be so prolonged and attended by so little disturbance of health, and followed by such very slight erysipelatous redness. Still the gradual increase of the local change, and the production of œdema, seem to definitely place the attacks in this category.

Another explanation is, however, possible, and it is that the attacks are indicative of liver disturbance. Mrs. B. has large patches of xanthelasma on her upper eyelids, the largest being, contrary to rule, on the right side. She has known of these for two years or more. She is also liable to attacks of dizziness and dimness before her eyes. Mrs. B. is sixty-two years of age, of a phlegmatic temperament. She says she cannot exist without fresh air, and is accustomed to sit in a draught of wind whenever she can.

Dupuytren's Induration of Palmar and Plantar Fasciæ, without Material Contraction.

A rather peculiar form of contraction of the palmar fascia was presented in the case of Mr. L. F. It occurred in his right palm only, and affected the fascia in front of the middle finger, and not that of the ring finger; and, although there was a long thick band of indurated tissue, there was comparatively little contraction. He had similar bands in the plantar fascia of each foot, but again without any obvious tendency to contraction. His age was 52. He was in tolerably good health, and there was no history of gout in the family.

As is well known, the prominent symptom in Dupuytren's disease is contraction. We

see every now and then, however, cases, such as the above, in which there is great induration and but little tendency to contract. In these, I think, the induration is more superficial than in the more common cases. I have just seen another case much like that of Mr. F. A long band of bossy induration extended up the palm in front of the ring finger, puckering the skin, but not drawing down the phalanges in the least. It is not common (as in Mr. F.'s case) to find the plantar fascia affected.

Asphyxia of the Extremities, beginning in Middle Life; Inherited Gout; Curious form of Cutaneous Tophi in Hands and Feet.

A very remarkable example of asphyxia of the extremities came under my notice in the person of a Miss B., in November, 1885. She was 60 years of age. Her hands were livid and cold, like those of a corpse (although she had been sitting for some time in a warm room), and her feet were almost in the same condition. Her legs, just above the ankle, pitted on pressure, the skin being pale and tallowy. The urine had been frequently examined, and never contained albumen. She could never put her hands into cold water, since it always made them die, and caused her a distressing sensation at the heart. Anything in the slightest degree tight on the hands or feet made them yet colder, and caused them to ache. Thus she had quite given up the wearing of gloves, and carried her hands in a large muff. Her feet were in loose fur-lined boots; and, when at home in the evening, she often found it more comfortable to take off her stockings. It was a very interesting question as to how far Miss B.'s condition was connected with gout. There was no doubt that she inherited it in an unusual degree. Her grandfathers on both sides had suffered severely from it. She herself had passed through an acute, definite attack of gout in the great toe, some years ago, at Aix-la-Chapelle, and she had had many less definite attacks of inflammation of joints. Twenty years ago, the late Dr. Falconer, of Bath, whom she had consulted on account of an inflamed knee, had told her that she was most certainly the subject of hereditary gout; yet, not a single joint had become crippled; she had no nodi digitorum, nor any tophi in her ears. She asserted that she had "often had chalk-stones come out of her fingers." On investigating this symptom, I found that she did not mean the ordinary discharge from large concretions about the joints, but the escape of little subepidermic masses, not bigger than shot. One of these she brought for my inspection, and she showed me in her fingers, and chiefly in her palmar aspects, many little pits, from which, she said, others had escaped. Some had also come away from the skin of her heels, but none from the toes. These concretions were coming away at the time that she consulted Dr. Falconer, twenty years ago, and were one of the conditions which caused him to declare that she was the subject of gout. In addition to the inheritance of gout, as possible factors in the production of her present condition, we must note that, in early life, she suffered much from biliousness, being habitually, as she said, yellow as a lemon; and, next, that in 1847, an influenza year, she had nearly died of that disease. She believed that her heart had been much weaker ever since that illness, and she had been told that, during her illness, they did not dare to move her, on account of its extreme feebleness.

Miss B.'s mode of life had always been careful. She took, in great moderation, home-brewed beer in early life. She was a lady of remarkable intelligence, great benevolence, and very active habits. As a fact for ophthalmologists, it may be recorded that she suffered from myopia; and had used the same spectacles for all purposes, from the age of 12 to that of 60, and still enjoyed perfect sharpness of vision. Her pulse was compressible, but by no means very feeble, having an intermission every ten beats. There was no evidence of calcareous disease of the arteries. I must now describe a very remarkable illness which Miss B. had recently passed through, and for the remains of which, in fact, she consulted me. She had all the spring "felt much gout about her." It was in November that I saw her, and she told me that in the preceding August (2d) she had awoke one morning, to find her left foot dead. It felt like wood, and was cold and livid. In the course of the following morning, severe pain developed in the sole and heel, and whole foot excepting the toes. The pain became intense, and finally passed upwards and settled in the back of the hip. At this part it was unbearable in severity, and was only relieved by a morphine injection. After lasting about twenty-four hours in the hip, it passed again to the foot, and settled in the sole. She was six weeks in bed with this attack, and could not bear anything to touch her foot; yet during this time it was not much swollen, but felt hard, and instead of being red and hot, remained cold and livid. She says that she was never out of pain, and

never slept. The deeply seated pain had not left her when she got up, nor indeed was she wholly free from it when I saw her. The whole instep was still swollen. She said that she had felt as if there was a raging fire in her foot, while its surface was still cold. Was this an attack of gout? If we reply in the affirmative, as I think we should be justified in doing, we have to meet the fact that all sorts of gout-medicine were used during the attack, without material benefit. She was under the able care of Mr. Willis, of Gloucester, in the first instance; and at the end of her illness Dr. Long Fox, of Bristol, was consulted. Miss B. was of dark complexion, and rather pale. She had enjoyed perfect regularity of menstruation, from the age of 15 to 35, and she considered that, since the cessation of the function, her health had not been so good as formerly. She had been liable to flushings and headaches, from which she had been previously free. Her hands felt, she said, wooden and awkward, from their coldness and slight swelling; but, as already stated, none of her finger-joints were in the least swollen or stiff. I examined her ears, and there were no traces of tophi or of chilblains. Her urine contained neither albumen, sugar, nor excess of acid.

I got some further facts, at a subsequent visit, as to the very peculiar form of chalk-stones which had occurred in this case. It is to be noted that they had never occurred except on the fingers and the heels, and that the liability to them had extended over twenty years. They formed in, or just under, the inner layers of the skin, and gradually worked their way to the surface, appearing as little dull white patches. Some of them inflamed before giving way; but others burst, and discharged their contents, without ever becoming, in any degree, either red or painful. The contents discharged differed much in different instances; sometimes a little dry powdery chalk; sometimes, chalk and water, or pipe-clay; and at others, a little nodular mass, as hard as bone. One of the latter kind Miss B. brought to me. It was about as big as the thicker half of a barley-corn, very hard and smooth, like bone.

What I subsequently learnt, made me yet more certain that the attack in the foot was, as diagnosed at the time by her surgeon, acute gout. The pain began in the middle of the night, and after an unwonted supper on beef. The numbness of the foot was probably due to the extreme severity of the pain in the tarsal joint, which was inflamed. I have known a case of acute gout of the shoulder-joint mistaken for paralysis of the upper extremity, on account of the helplessness and numbness of the limb, which were induced, I believe, by the extreme severity of the pain in the joint.

The peculiarities of the attack; the coldness of the part, instead of heat; and its lividity, instead of redness, were, no doubt, due to the previously existing peculiarities in Miss B.'s circulation. Turgescence of the venous system is, under many conditions, a noticeable feature in gout. We may ask the question, whether, in Miss B.'s case, the gout tendency had anything to do with the production of the general asphyxia of the limbs. I saw, some years ago, a gentleman, a member of our own profession, aged about sixty-five, in whom there was good reason to suspect gout, and who, subsequently, had a chronic enlargement in the joint of one of his fingers, and a very peculiar condition of one toe. It became a little swollen, blue, and livid, and remained so for a month or two. We were very anxious lest it should pass into gangrene; but the condition was unattended by pain, and eventually it passed completely away. In Miss B.'s case, at the time of her second visit, I again carefully observed the state of her circulation. Her fingers, on this occasion, were not either livid or cold; for the day was warmer, and she had been sitting in a very warm room. Notwithstanding this, however, her feet were cold, and as blue as those of a corpse. I noticed that her hands, which were cold and of a dull-red color, were rough and coarse, like those of a laboring man, and her nails were broad and somewhat roughened. She complained that all her fingers felt thick and awkward; they were "all like thumbs." When we remember the remarkable tendency to the formation of subcutaneous tophi on the hands and feet, and on these parts only, the conjecture becomes, I think, not improbable, that the venous circulation, in parts which had long suffered from definite gout, may have become permanently altered by it.

As regards diet, Miss B. has possibly not managed herself quite well. In early life, she took home-brewed beer regularly, in small quantities. Dr. Falconer told her, twenty years ago, to avoid beer as poison, and she did so with decided benefit. She continued, however, to take wine irregularly—that is, occasionally, when feeling to need it; and she has consumed meat rather largely. I advised that she should cautiously put herself on partial vegetarianism, and take, as a stimulant, whisky and water only. She said that she was very dependent on meat, and

never felt at her best until she had had her meat-meal.

Case Illustrating the Effect of Removal of the Fallopian Tubes.

Dr. Chas. E. Jennings thus writes in the *Medical Press:*

The following case may assist in settling two questions which have lately been the subject of controversy:

1. The dependence of menstruation upon the ovaries or upon the Fallopian tubes.

2. The importance of uniting surfaces of peritoneum (after the abdominal wall has been divided) as a means of preventing ventral hernia.

On January 13, 1886, I operated for the cure of a ventral hernia upon a married lady in her forty-first year, who furnished this history. She is the wife of an Indian officer, and had been operated upon by Mr. Lawson Tait in October, 1884, at Birmingham, from whom she obtained the following certificate:

"7 The Crescent, Birmingham,
"January 4, 1886.

"Mrs. W—— came under my care in October, 1884, when I found her suffering from metritis, retroversion, and complete fixation of the uterus, with all the symptoms of double hydrosalpinx. For this I performed abdominal section, and found both ovaries thoroughly disorganized, and both tubes occluded and distended with serum; I therefore removed the uterine appendages.

"From this operation she made a complete recovery, with the exception that having been somewhat inattentive to the directions for wearing her belt, the tendinous elements of the cicatrix have been stretched, and there is a slight tendency to enterocele. I am, however, of opinion that this is so slight as to be of no great consequence, but only a slight inconvenience. "Lawson Tait."

From several of the patient's letters now in my possession, this account of her progress since the performance of Mr, Tait's operation (October 4, 1884) is abstracted:

"Great pain was suffered till a supporting belt and pad were applied. Menstruation set in January, 1885, and continued at regular intervals for five months. The last I saw of it was on the 15th of June, 1885 . . (until) it appeared on the 28th of September, 1885, lasted four days. Again on the 28th of October, 1885, five days. Again, on the 18th of November, 1885, lasted eighteen days . . A drive in a carriage, or a few miles in a train, will cause it to re-appear."

The physical condition presented in January, 1886, was a ventral hernia of the size of about half-a-crown, situated in the centre of a cicatrix, midway between the umbilicus and symphysis pubis, resulting from Mr. Tait's operation.

The case seemed very suitable now for operation, because the patient wished to rejoin her husband in India as quickly as possible. She was a woman accustomed to very active outdoor occupation, viz., riding, driving, walking, and swimming, and the existence of the rupture was a great bar to her following the mode of life which her husband's appointment in India made imperative upon her.

January 13, 1886. Chloro-methyl having been administered, and the usual antiseptic precautions, including the spray, having been strictly observed, the integument was divided in the line of the cicatrix over the hernial protrusion. The omentum was found adherent to the circumference of an aperture in the linea alba, which appeared to have persisted after the removal of the drainage-tube, which was stated by the patient to have been employed by Mr. Tait, and to have been removed seven days after his operation.

The adherent protruding omentum was separated, and the uterine region was explored. Both fallopian tubes had been removed, as well as the right ovary; but on the left side a mass, about the size of a small apple, was discovered at a point corresponding with the normal site of the left ovary. On attempting to draw this up a cyst gave way, and about an ounce of fluid escaped. The solid remaining part of the mass was about the size of the kernel of a walnut. This was removed after the application of a ligature in the ordinary manner. A few adhesions between the upper and posterior part of the uterus, and some neighboring coils of small intestine, were separated. The portion of omentum which had protruded, and was adherent, was separated from its attachments and cut away. Only one omental ligature was required. The peritoneal cavity was cleansed and the abdominal wound carefully united with interrupted silk sutures passed through the parietes in such a manner as to insure complete contact of the peritoneal surfaces. A pad of iodoform wool (10 per cent.) was placed over the sutures; strapping and a binder were applied.

With the exception of some vomiting which followed the operation, there was nothing to cause any anxiety, and on the eighth day all the stitches were removed. The wound had closed firmly, save for about half an inch, where the skin had not united,

but in a few days this had closed satisfactorily. The ventral hernia has been completely cured, and the lady is about to return to India in good health.

Dr. Klein kindly examined the growth which I removed, and reported that in part of it there "was no doubt of the structure of ovarian tissue."

We may therefore conclude from this case that removal of both fallopian tubes and of one ovary does not necessarily interfere with menstruation. In this case, where one ovary, or perhaps part of an ovary, was not removed, menstruation continued with but slight irregularity.

Mr. Lawson Tait has recently published a list of 139 *consecutive* cases, of what he calls ovariotomies, performed between January 1, 1884, and December 31, 1885. The patient whose case is narrated was operated upon by Mr. Tait in October, 1884, but no record of this case appears in his published list, although he publishes the statement that "in the period embracing this series of 139 successful cases, there has not been in my practice a single incomplete operation."

Neuritis, following Traumatism. Treated in Various Ways, Finally by Resection of a Portion of the Nerve—Cure.

Dr. E. Stanmore Bishop thus writes in the *Medical Chronicle*:

Miss K., unmarried, æt. 34, has long suffered from neurotic attacks, culminating from time totime in epileptiform seizures, but on the 29th of March, 1885, she first complained to me of pain in the right breast, apparently seated in a small lump on the lower and exterior portion of the mammary gland. She had felt this mass for some years, and attributed its appearance to a fall down a man-hole some ten years before, but it had never given pain. I diagnosed a simple adenoma, which turned out to be correct, and advised that, if pain continued, it might easily be removed. This was done April 14; the wound healed fairly well, but the line of union gave way once or twice to allow of the extrusion of knots of catgut ligature; and when it finally healed great pain was felt in the scar, and radiating backwards and forwards from this point along the intercostal nerve. Numerous anodyne applications were ordered, but uselessly, and the pain became steadily more intense. Pain was also found on percussion over the third and fourth dorsal vertebræ. Neuroses, herpes of the skin over the line of nerve, especially over the breast, appeared, and the intervals became glossy. Thinking that these symptoms were due to pinching of some nerve-ends in the scar, a tenotomy knife was introduced on the outer side, and scar freed, July 2. Still the pain continued; but besides this, a large effusion of blood took place beneath the skin; this became inflamed and suppurated. Opened July 13. The pain was easier as soon as a free opening was made, but returned, if possible, with greater force as soon as the wound closed. The breast now began to feel heavy subjectively, and the patient appeared to be in great pain. The breast was slung; anodynes used internally and externally; phosphorus, quinine, and potassic bromide used steadily, with chloral or opium from time to time to procure sleep, but with no effect as regards the pain; and the patient began to beg for the removal of the breast, which appeared to her as of great weight and very painful. I decidedly objected to this as unnecessary; but at last, in September, in consequence of her strong wish, this was done, and again relief was obtained as long as the wound was open, although the cut surfaces did not tend to heal kindly, and the herpetic condition of the surface still remained. At last the scar formed, and with it returned the old pain in all its intensity. Again all medical means were tried afresh, and for a long period, it being thought that possibly the recurrence was due to the peculiar neurotic character of the patient, but no abatement could be obtained. Then the actual cautery was applied to the spine over the vertebræ answering to the origin of the nerve affected, and also to the lateral branch of the same nerve. All these points were easily determined by the patient without any guidance. The cauterization was thoroughly done twice, but no good appeared to have been effected, and as a last resource it was determined to resect a portion of the nerve. This was done on the 7th of February, 1886, the nerve being reached by a vertical incision from the posterior wall of the axilla, cutting through two serrations of the serratus magnus. The nerve was found lying outside of the external intercostal muscle. Half an inch was removed, and found to be in a state of neuritis. On recovery from anæsthesia, the patient found that the pain was gone; and no return has occurred up to the present time. The wound rapidly healed, and the patient was shown to the Manchester Medical Society at the meeting in April this year.

—The New York City Board of Health last year destroyed more than a million pounds of spoiled food.

On a Case of Imperforate Anus.

Sir William MacCormac thus writes in the *Lancet*, July 3:

The particulars of this case may be worthy of record, as illustrating a practice somewhat different from that usually adopted.

On March 21, 1886, I was requested by Dr. Duncan, of Henrietta street, to see a child born two days previously. The anus was well formed, but almost immediately terminated in a pouch about half an inch beneath the surface. On careful and repeated examination, no trace of impulse or proximity of the bowel could be made out. We decided, therefore, that it was preferable to perform colotomy in the left groin, rather than undertake what promised to be a hopeless search for the bowel in the natural situation. A small incision was made in the usual place, and after the structures had been divided in succession, the intestine at once presented in the wound; it was sutured to the skin, and afterwards opened. Meconium escaped, and the abdominal distension, which before was very considerable, shortly subsided. The operation created no disturbance; the child took its food eagerly, slept well, and there was no sickness. The intention was at a later period to pass a probe or blunt instrument from the opening in the sigmoid flexure downwards towards the anus, and in this way ascertain the condition of the rectum, to what extent it might be deficient, and how far distant it terminated from the external *cul-de-sac*. On April 12th this was accordingly done, and, contrary to expectation, only a quite thin septum was found to exist between the rectum and the anus. It was divided with great ease upon the rounded extremity of a director, which was caused to project, and a free opening established, a well-perforated drainage-tube being subsequently passed from one opening to the other to facilitate the bowels being washed out, and to prevent the opening into the groin closing, which it showed a disposition to do. The child made an equally good recovery from this operation, and continued perfectly well for some days; then symptoms of acute peritonitis suddenly set in, and it died on April 17th.

On examination after death, there was a considerable amount of lymph and fluid in the abdominal cavity. The upper portion of the sigmoid flexure had been opened, and was firmly attached to the abdominal wall. The rectum was found full of a semi-solid mass of fæcal matter, evidently of some duration, and this condition no doubt accounted for the total absence of impulse in the region of the anus. The rectum was found to be complete, with the exception of the septum already spoken of; and there was nothing found in the region of either operation to account for the fatal result. After removing and slitting open the intestine, a small perforation was found in it about midway between the opening in the groin and the anus, and resting against this a small scybalous mass of fæces. It was as the result of the ulceration and perforation of the bowel at this point that peritonitis took place.

In those cases which are frequently met with where the bowel terminates at an unknown distance from the anus, the performance of Littré's operation gives the child immediate relief, and is attended by comparatively little danger; time is gained for considering what the next step should be at a time when the child is older and better fitted to bear a further operation; and from the opening in the groin the condition of the extremity of the bowel can be ascertained with tolerable accuracy. When practicable, the natural channel can be re-established with the great aduantage of having an exact guide to the position of the extremity of the gut, an advantage which all will appreciate who have had to make the difficult and often fruitless search for the blind extremity of the bowel in cases of imperforate anus.

Poisonous Ginger Beer.

At a recent meeting of the Aberdeen, Banff, and Kincardine branch of the British Medical Association, Dr. Presslie (who until graduation was a pharmacist) read an interesting paper on two cases (out of a series) of poisoning by fermented ginger beer. In one case, that of a very temperate man in an easy situation, dyspeptic symptoms had lasted for two years, and the patient had lost much flesh. One day he was found shivering, having vomited a brownish substance, smelling of alcohol. The temperature rose gradually and then fell. The patient recovered, and resumed work. The vomit consisted of schizomycetes and saccharomycetes, which underwent the alcoholic, acetic, and butyric fermentations. Ginger beer gave such a ferment, which would multiply with great rapidity. In both cases the patients indulged in this liquor. The similarity of the symptoms in these two cases, and their recurrence in seven days, was interesting; and their causation could not be referred to the alcoholic or acetic ferment, or sarcina ventriculi. Dr. Presslie is pursuing the subject.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

A PRAISEWORTHY HYGIENIC ENTERPRISE.

Mainly with the object to reduce the enormous death-rate which occurs amongst young children in Berlin just as much as in all large cities, the physicians of Berlin have recommended to the councils of that city the erection of two "milk halls," and as we see from an article in the *Deutsch. Med. Zeit.* (June 17, 1886), there is every prospect of the enterprise becoming a grand success.

Two large lots, each comprising nearly a whole acre, and belonging to the city of Berlin, have been selected for this purpose. Both are not far removed from the centre of the city, and lie near public squares, so that good air is insured. It is the intention first to build model stables, in which a certain number of the best Alderney milk cows are to be kept. Then besides the buildings for the inspector and for the other officers and servants of the institute, a large hall is to be erected, where the milk is sold, and where it may also at once be drank. Twice a day the cows are milked, and for every child that is to be provided with milk, a ticket is issued containing a number corresponding to the same number of the cow and of the vessels used for milking, the transport of the milk, and if such is required, for drinking, thus insuring for every child its continually receiving supply from one and the same cow. The same regulation will be carried out with the milk sold; the parents of the child receiving a special vessel for the transport of the milk, numbered in the same way.

To be sure, the city of Berlin cannot go into the milking business; the ulterior object must not be lost sight of. The following rules will therefore be guiding in the sale of the milk:

A child, to be supplied with milk, must have a certificate from a regular physician, containing, besides other points of information, as name, age, residence, etc., about the quantity of milk needed during 24 hours.

The milk is given out only twice a day during stated hours. Though the vessels, in which the milk is sold, are expected to be returned well cleaned, two vessels are kept for each child, the one returned being kept in the institute until the next delivery, it being meanwhile thoroughly disinfected.

The chief inspector of the institute is a physician. No milk is delivered unless the inspector has first examined the cow concerning her healthy condition, and also the milk, to satisfy himself of the same regarding it. This inspection must take place twice every day. All the feed needed for the cattle must also first pass his inspection before

it can be used, and the same scrutiny the stables, the straw for the night, and all the vessels used have to undergo. Naturally, all the employed have to be free from disease, and those entrusted with the milking or with the handling of the milk or of the vessels, have to disinfect their hands at certain hours of the day, and in a manner directed by the rules. They are dressed in summer in a blue linen suit, while in winter such a one covers their other clothing, and special directions are given to insure its aseptic condition.

In other words, the utmost care will be taken to prevent infection, while the milk will be sold at cost. Would it not be well for Philadelphia to have a few such institutions?

TREATMENT OF WHOOPING-COUGH.

During the last six years or more, quinine has been recommended over and over again as the best remedy against whooping-cough. Several authors insisted that the remedy should be given in powder form, or if in solution, that it should be kept as long as possible near the pharynx. Nobody has yet given the reasons for this procedure, but reliable authorities united in saying that most success is obtained where the remedy is kept the longest in contact with the pharynx.

Dr. Kohlonetz conceived, recently, the idea of injecting the remedy in solution with considerable force far back into the mouth against the walls of the pharynx (*Deutsch. Med. Zeit.*, June 17, 1886). In this manner he believes that some of it gets into the larynx and that the larger quantity of it comes into intimate contact with the epiglottis, a fact he considers of the utmost importance. He employs the following formula:

℞.	Quiniæ sulphatis,	gr. lxiv.	
	Acid. sulphur.,	♏ xxxij.	
	Aq. destillat., ad	f. ℥ vj.	M.

S.

During the first three days he injects a common glass syringeful of this solution every two hours into the open mouth, the tongue being depressed by the mother with the aid of a spoon. The next four days these injections are made every three hours, and after that ad libitum. This dose is used in children from three to four years. In younger children the method and its execution are the same, the only difference being that the syringe is not filled quite so full.

The result has been remarkably good. As a rule, the whoop greatly diminished by the third day, and in almost all cases, ceased totally by the end of the first week. Whenever the result was not so satisfactory, K. convinced himself that the treatment had not been carried out strictly according to directions, and he requests physicians to give the method a fair trial. As it can easily be executed, we advise our readers to do the same. Some children suffer so intensely from this disease, that anything promising relief may well be worth a trial.

PROGRESS IN MEDICINE.

The question, whether medicine is a progressive science, may seem, to a physician, scarcely necessary to ask. But by the skeptical world it is often answered in the negative. Dr. Morell Mackenzie, therefore, has done good service by preparing an article in the *Fortnightly Rewiew* (June, 1886), in which he indicates its advances and points out the lines of progress.

He clearly shows that this is not where the public generally expect and ask it, that is, in the discovery of remedies which will cure diseases, but rather in their prevention, and in forestalling and mitigating their painful symptoms. To quote his words on this point:

"In nothing is the progressive character of the healing art more conspicuous than in the constant additions which are made to our means of dealing with troublesome symptoms, which, even if they do not threaten life, make it miserable and perhaps useless. If it be the destiny of mankind to have disease always going about among them, seeking whom it may devour, it is still much that more and better safeguards should be found against it, that its ravages should be lessened, and that our life, into which, brief as it is, such an amount of suffering may be compressed, should be rendered less and less subject to pain, and freer from bodily discomfort. On this ground alone medicine may well take its stand as a progressive science."

Dr. Mackenzie adds some excellent suggestions how this progress could be hastened. He points out that the practice of medicine is and must be with most a means of livelihood, and that to pursue it chiefly for the discovery of truth is a sure way to forfeit its pecuniary profits. Then popular prejudice interferes with it, as that against vivisection, that against the medical execution of criminals, and in places against anatomy and post-mortems. His suggestions are eminently timely, and we trust will not prove ineffective.

Notes and Comments.

The Pneumonia-Coccus of Friedlander.

Dr. George M. Sternberg, U. S. A., in a paper which appears in the July number of *The American Jour. of the Med. Sciences*, calls attention to the so-called pneumonia-coccus of Friedlander, which he claims is, in fact, identical, specifically, with a micrococcus which he previously described, and which is found in normal human saliva, and with that found by Pasteur in the blood of rabbits which had been injected with the saliva of a child which died of hydrophobia in one of the Paris hospitals. This micrococcus he names *Micrococcus Pasteuri*. The capsule, or mucous envelope, which sometimes surrounds this micrococcus, described by Friedlander in 1883, and photographed by Sternberg two years previously, cannot be accepted as a distinguishing character of this species, inasmuch as it is not constantly present, and the circumstances upon which its development depends have not been accurately determined. It is established that this is a pathogenic organism, as far as certain lower animals are concerned, and that its pathogenic power varies under different circumstances. It seems extremely probable that this micrococcus is concerned in the etiology of croupous pneumonia, and that the infectious nature of this disease is due to its presence in the fibrinous exudate into the pulmonary alveoli.

But this cannot be considered as definitely established by the experiments which have thus far been made upon lower animals. The constant presence of this micrococcus in the buccal secretions of healthy persons indicates that some other factor is required for the development of an attack of pneumonia; and it seems probable that this other factor acts by reducing the vital resisting power of the pulmonary tissues, and thus making them vulnerable to the attacks of the microbe. This supposition enables us to account for the development of the numerous cases of pneumonia which cannot be traced to infection from without. The germ being always present, auto-infection is liable to occur whenever from alcoholism, sewer-gas poisoning, crowd-poisoning, or any other depressing agency, the vitality of the tissues is reduced below the resisting point. We may suppose also that a reflex vaso-motor paralysis, affecting a single lobe of the lung, for example, and induced by exposure to cold, may so reduce the resisting power of the pulmonary tissue as to permit this micrococcus to produce its characteristic effects.

Again, we may suppose that a person, whose vital resisting power is reduced by any of the causes mentioned, may be attacked by pneumonia from external infection with material containing a pathogenic variety of this micrococcus having a potency, permanent or acquired, greater than that possessed by the same organism in normal buccal secretions.

Man is Often Sterile.

After discussing the causes of sterility (*Med. Press*, July 7), Dr. Alfred S. Gubb thus concludes:

"When, after due investigation, nothing has been found to explain the incapacity of the reproductive apparatus, inquiries should be made as to the function in the husband. Dr. Pajot insists very strongly on this, and maintains that the old idea of the rarity of sterility in man is not justified by the result of his own observations on the subject. It is important to bear in mind that the absence of spermatozoa from the semen is quite compatible with vigorous sexual appetite and capacity. Even if spermatozoa be found, as in the semen of aged men, their immaturity and feeble vitality may amply account for their uselessness from a procreative point of view. The husband should be closely questioned for any history of gonorrhœa and orchitis, and a specimen of the semen should invariably be obtained and examined under the microscope. Even when the result of our examination is unfavorable, it is not desirable to impart the information to the patient, for, apart from the extreme mental depression which is apt to follow such information, great domestic inconvenience might arise, if, in consequence of an error in diagnosis or otherwise, a pregnancy subsequently occurred. It is important to make use of the same objective for microscopic examination on every occasion, as any differences in size and appearance on the part of the spermatozoa will thus be better appreciated."

Deformity of Neck.

To the Liverpool Medical Institution, Mr. Robert Jones exhibited a boy, æt. 13, who having fallen into a pond contracted acute rheumatism in 1882, during the course of which his neck became drawn to the left side, in consequence of inflammation and one-sided thickening of the cervical vertebræ. Five months later he was sent to a large northern infirmary, but it was thought use-

less or indiscreet to attempt to correct the deformity. Two years later he was sent to Mr. Jones from Ripon, and admitted into the Stanley Hospital. The right angle of the lower jaw was lying upon the left sterno-clavicular articulation. The cervical vertebræ were enormously hypertrophied and painful on pressure. The patient complained of dyspnœa, and spoke with difficulty. The pupil was widely dilated, owing to pressure on a sympathetic. The face looked parallel to the left clavicle. The head was very firmly fixed, and produced no yielding sensation on manipulation. The treatment consisted in wedging and levering the head very gradually, and after a time fixing a cervical collar. Later, placing him in the "key-note" position, and fixing an iron framework around his head, while rotation was attained by means of elastic bands. The breathing and articulation were soon relieved, and in four months the chin was four inches from the clavicle, opposite the sternum, and the patient had the power to rotate his head three inches, with the ability to use moderate flexion.

Sedatives and Electricity in Tetanus.

Dr. M. L. Moreau publishes, in the *Alger Médical*, January and February, 1886, notes on a case of tetaniform symptoms cured by rest, sedatives, and electricity. The patient had trismus and opisthotonos, without any apparent reason; his intelligence was intact. He recovered in four days, during which period morphine and chloral were given in full doses, and the patient was kept thoroughly at rest, and was enveloped in cotton-wool. The patient had presented similar symptoms fourteen years previously, in consequence of injury to the scalp from a nail. On the present occasion, another equally insignificant reason was suggested. The patient was a neuropath, and in order to obtain relief from his condition, he covered his body with needle-punctures, by using an instrument similar to a cupping apparatus. These recurring tetanic attacks indicated a constitutional predisposition which M. Moreau sought to explain by hysteria, but the symptoms were not sufficiently marked to justify this diagnosis, nor was there any evidence of poisoning by strychnine. A carefully kept register of the patient's temperature during the attacks would perhaps have furnished some data, but this was not done. The most probable hypothesis was that repeated cutaneous irritation, practiced on a neurotic patient, provoked accidents of a tetaniform character.

Diphtheria.

Dr. De Luskie Miller gives the following formula in the *Jour. Am. Med. Ass.*, July 3:

℞.	Tr. ferri chloridi,	ʒj.
	Potas. chlorat.,	ʒij.
	Acid hydrochloric dil.,	♏xx.
	Tr. capsici,	ʒj.
	Morph. muriat.,	gr. ss.
	Glycerine,	ʒij.
	Aq. destil.,	ʒijss.

M. S.—Give a teaspoonful every hour or two or three hours, according to the urgency of the symptoms.

Of course the proportions of the several ingredients will be varied in different cases, to adjust the doses to the age and condition of the patient. The directions for taking the mixture given above, however, convey but an imperfect idea of the most efficient mode of using it. The patient should be required to take a drink of water, then immediately take the mixture undiluted. By this mode several indications are fulfilled at one and the same time. An efficient local application is made to the throat each time the mixture is administered, and the constitutional tonic, antiseptic and anodyne effects are also secured. The water which was taken before the medicine will be sufficient to properly dilute the remedies in the stomach, and thus prevent any irritation of that organ.

Gunshot Wound of Knee-joint—Recovery.

Dr. John Rodman, of Abilene, Tex., reports to the *Med. Record* the case of a man who was shot horizontally through the knee-joint with a "bull-dog" pistol, the ball ranging outward. A large quantity of synovia was evacuated, and as the joint was entered, the bone was found to be shattered, one spiculum of which was removed at the time the ball was spent by the bone, and was extracted from the fascia on the outer side. The probe grated over a large surface of comminuted bone, and came in contact with pieces of bone that could not, however, be removed through the wound. The latter was irrigated and cleansed with corrosive sublimate solution and hermetically sealed, a posterior splint being applied. The temperature was but 99⅕° on second day, and was normal on the fourth day and afterward. The dressing was removed fifteen days after the receipt of the injury, and no pus could be found. The joint is now being flexed daily, and the prospects are that no stiffness will result. Dr. Rodman says that in his past experience of knee-joint wounds (from railroad injuries solely), he has never known

a recovery, even after amputation, when the joint was opened and the bone comminuted.

Tetanus Cured by Removing Compression from the Radial Nerve.

A remarkable case of traumatic tetanus was recently cured by the removal of compression from the radial nerve. A boy, aged 14, was admitted to Conrad Brunner's wards at Zürich, for a fracture of the left radius which had occurred three weeks previously. The fourteenth day after the fracture the child observed that he could not stretch the fingers of the left hand; his parents noticed that, when he walked, his body was bent forward. The symptoms became more and more marked; the child had bad nights, and was sent to the hospital. Symptoms of tetanus, risus, trismus, and emprosthotonos were marked. On examining the patient there was evidence of a fractured epiphysis of the radius badly reduced, and a bulky callus just below the articulation. It seemed evident that the tetanus resulted from compression of the radial nerve by the callus. The parts were exposed by incision, when it was found that there was pressure of the nerve by new formations attached to the callus. The compressed nerve was set free, and the prominent portion of the radius resected. The symptoms of tetanus slowly disappeared; the patient had morphine injections. Three weeks after the operation the patient was cured.

Disease following Circumcision.

The *Med. Press* says that at a recent meeting of the Royal Society of Physicians of Vienna, Professor Hofmokl showed an interesting case of tuberculosis following circumcision. He pointed out that von Bergmann, of Berlin, had first drawn attention to the dangers attending the rite at the last meeting of the Surgical Congress. The case shown was that of a boy eight months old, the son of healthy parents, who was circumcised on the eighth day. The mother stated that the bleeding was checked by sucking the wound. The wound did not heal, and at the end of six weeks a small grey-covered ulcer was observed on the remains of the prepuce on the dorsum penis. The inguinal glands were slightly enlarged, but there was otherwise no sign of syphilis. Anti-syphilitic treatment failed. The ulcer was then scraped, but with no better result, and some of the glands suppurated. Tubercle bacilli could not be made out. It was his intention to extirpate the glands one after another. Professor Kaposi said that he had seen a whole series of similar cases, and they were all syphilitic. He recommended inunction of ung. hydrarg. over the glands. Professor Hofmokl said that he had tried the plan recommended, without benefit.

The Use of the Catheter in Paraplegia.

Writing about ataxic paraplegia in the *Lancet* (July 10), Dr. W. R. Gowers very truly says that whenever there is retention of urine, or whenever the bladder is imperfectly emptied, the condition must be dealt with by appropriate local treatment. Remember that kidney disease, secondary to cystitis or to mere distension of the bladder, is a common cause of death in all diseases of the spinal cord. In ataxic paraplegia this danger, if not absolutely great, is relatively greater than in many other diseases, because other sources of danger to life, such as bed-sores or interference with respiration, are insignificant. There is no doubt that this danger may, to a large extent, be obviated. "I have not in any case, or in any disease, seen an evil result from the early and frequent use of the catheter, and I have known more than one patient die whose life might have been saved had residual urine been regularly removed and the bladder repeatedly washed out. I know patients who are now alive who would, I am sure, have died had this treatment not been adopted. The simple reflex incontinence in which the bladder is perfectly emptied from time to time calls for no interference."

Purpura Hemorrhagica after Scarlet Fever.

In the *Memorabilien* two cases are recorded of purpura hemorrhagica following scarlet fever, in sisters, four and nine years old respectively. In the first case the purpura set in three weeks after the commencement of the disease; in the second in the fourth week. In both cases there was hematuria. There was no swelling of the gums, and the cases were distinctly marked off from scurvy, which the author has had abundant opportunity to study. There was no family history pointing to the purpuric diathesis, but both children were slightly scrofulous. Both recovered. The urines exhibited the following features: Directly on pouring some urine on hydrochloric acid the indigo reaction occurred, with a copious dark-blue deposit. When the urine was allowed to stand about eight days there appeared on its surface a scum with a metallic glaze. Presently a blue film shot across

the surface, and after a time the whole urine became blue. Microscopic examination of the urine showed indigo flakes and dark-blue heaps of micrococci in unusual numbers.

Myelitis or Reflex Paraplegia (?)

Before an English medical society, Dr. Black showed a man of fifty-three, admitted into the County Hospital with partial loss of motor power in the legs, and of control over the bladder and rectum; most of the reflexes were exaggerated, the gait was stiff and spastic, but there was no marked wasting and no rigidity; the urine was alkaline, and free from albumen; there was much vesical pain; there was no stricture, but chronic dysuria, and retention, requiring the catheter, had occurred seven weeks before; about the same time he rather suddenly lost power in the legs. On the other hand, in favor of the syphilitic origin of the symptoms (from a disseminated myelitis) was the history of chancre and secondary symptoms two years previously. He was ordered one grain of mercury with chalk three times a day, and from five to ten grains of iodide of potassium; the bladder to be washed out daily with boracic acid solution; and under this treatment all the symptoms had improved in a few weeks.

Stretching of the Facial Nerve.

The operation of nerve stretching was first introduced by Billroth and Nussbaum in 1872. It has been done only twenty-one times upon the facial nerve so far as Dr. W. W. Keen (*Annals of Surgery* for July) has been able to ascertain. Five of these cases have been done in America (Putnam two, Gray two. His own is the fifth.) All of the cases have been for more or less extensive tic non douloureux of the face, lasting from two to ten years. In two cases paralysis of the face preceded the convulsive tic, and in one case tic douloureux followed the tic convulsif.

Dr. Keen concludes: It would seem, therefore, that whether viewed from the point of palliation or of cure, the operation is, with our present knowledge, to be looked upon favorably. Further observation may show its inutility, but when we consider the utter hopelessness of improvement, much less recovery, from any other means, relief by this operation, even if temporary, is had at a very trivial cost, and would be welcomed by any sufferer, while permanent cure is not impossible.

Two Cases of Serious Symptoms from Foreign Bodies in the Ear.

Before a recent meeting of the Cambridge (England) Medical Society, Dr. Ingle mentioned two instances in children, in which marked cerebral irritation and pyrexia were produced by the presence in the ear of foreign bodies. In the one case a swollen dead lady-bird was extracted by syringing, in the other some wax and a dried pea. He offered in explanation that the symptoms were produced by pressure on the branches of the third division of the fifth nerve and the vagus, which supplied the cutaneous lining of the canal and drum; further, pressure upon the vaso-motor fibres of the sympathetic might lead to the irritation of certain areas; and these changes would be more likely to occur in children from the small size of their ear-passages, and from the fact that in both cases the foreign bodies were capable of enlargement from the absorption of moisture. Dr. Ingle was in favor of syringing as the safest and best method of removing foreign bodies from the ear.

Jamaica Dogwood.

Dr. F. Spencer Halsey, of New York, reports fourteen cases wherein he used this drug as a hypnotic in *The Therapeutic Gazette* (July 15), and thus concludes:

"These few cases, culled from a number of months' experience in hospital practice, have led me to express my opinion as to the value of Jamaica dogwood. I have found it to be a most excellent hypnotic and anodyne; in no one case of those in which I employed it, has it failed to relieve pain and induce sleep. One great advantage connected with it is that patients, after taking it, awake with none of the unpleasant after-effects which opium induces. Not only does it relieve pain and produce sleep, but in many cases it relieves cough, notably the case in phthisis. This experience, though very limited, has induced me to become very much attached to this remedy; and in every case where such an action as comes from its use is indicated, I have always employed it with most satisfactory results."

The Influence of Syphilis upon Non-Syphilitic Eruptions of the Skin.

Dr. J. Clark McGuire thus concludes a paper in *The American Practitioner and News* for July 10:

"In the foregoing remarks I have endeavored to show the importance of recognizing the *possibility* of constitutional syphilis modi-

fying certain non-syphilitic eruptions. I would not be understood as declaring that all eruptions of the skin occurring in syphilitic subjects were of necessity altered in their appearance and usual characters, but simply that such changes are *possible* and do occur in a certain number of cases. I am of the opinion that, unless such an influence is considered, we will many times fail in our diagnosis; in consequence, our prognosis will be at fault, and the treatment instituted will avail nothing in a disease so modified unless the syphilis is treated in conjunction with it."

Peculiar Skin Disease of the Feet.

Before a recent meeting of the Montreal Medico-Chirurgical Society Dr. R. J. B. Howard exhibited a boy, twelve years of age, of healthy family. He has angular curvature, involving the lower dorsal region, first noticed when he was three and a half years old. His feet were first affected in his sixth year. A small "scurfy" spot appeared first on the right foot, and has spread steadily, healing at the centre. When he came to the Dispensary it appeared as a lupiginous patch about four inches across, on the right ankle and instep; smaller similar patches existed on the outside of the right little toe and left great toe, at metatarso-phalangeal joint. The patch is covered with a crust or scab of a somewhat papullary appearance. Not tender or painful at any time, and never ulcerated. Dr. Howard brought the case for diagnosis. He thought it was due to some derangement of the spinal cord at the seat of the curvature, as nerves from this region supplied the skin of the feet.

Carbolic Acid as a Hypodermic Injection for the Cure of Hemorrhoids, Carbuncles, etc.

After relating several cases where most satisfactory results were procured, Dr. N. B. Kennedy concludes in the *Atlanta Med. and Surg. Jour.*, that in carbolic acid we have one of the most powerful remedies for good in the whole pharmacopœia.

In one instance, a highly nervous young lady came to his residence to have a felon lanced. She was clamorous for chloroform, as she feared the pain would kill her. He bathed the finger in pure undiluted acid, and in two minutes lanced the felon almost without pain, much to her astonishment.

Into hemorrhoidal tumors he injects from twenty to sixty drops of pure, undiluted acid: so also with carbuncles.

Corneal Changes in Acquired Syphilis.

Before the Ophthalmological Society of Great Britain, Dr. M. J. Symons contributed the history of a case of double symmetrical changes in the cornea of a man aged twenty-nine, who had acquired syphilis eight years earlier. The patient had first noticed that his eyes were weak, and that there was a film upon them seven weeks before he came under treatment. At the latter date there was thinning, bulging, and opacity over limited areas of both corneæ, without any disturbance of the epithelium. The iris was partially adherent in both eyes. The other tissues of the eye appeared to be healthy. Iodide of potassium effected but slight improvement in a fortnight, when the patient left the hospital.

Lead-poisoning from Eating an Apple.

The *Journal de Medecine de Bruxelles* reports that a lady who had previously enjoyed perfect health was suddenly taken with violent colic, which, although very severe, passed away, and the next day she consulted a Parisian physician, who diagnosed lead colic. No possible source of the lead could be suspected, however, until the lady called to mind that the day before the attack she had eaten an apple in which she had found, on eating, a shot pellet. It was then concluded that this pellet, in combination with the malic acid of the apple, was the cause of the attack. The story shows, at any rate, what expert *shots* Parisian as well as other physicians sometimes are at a diagnosis!

Lymphadenoma of the Intestine, with Leukæmia.

M. Mathieu reported at a recent meeting of the Paris Anatomical Society the case of a man, aged sixty, who had suffered from uncontrollable diarrhœa for five or six months, with glandular enlargements in the groin and axilla. He was very cachectic, and anasarca was present. The blood was examined several times without any signs of leukæmia being detected. At the necropsy the solitary glands were found much swollen and of a pearly white color, Peyer's patches being healthy. The mesenteric glands were much enlarged, also the spleen, the liver and kidneys being healthy. No tubercle was found.

Bromide of Potassium and Lotions of Ether for Sunstroke.

The plan pursued by Dr. C. H. Hughes (who makes a note of his method in the

Weekly Medical Review), is to give from sixty to one hundred and twenty grains during the first hour, and sixty grains every hour, or thirty grains every half hour, largely diluted in peppermint water; sulphuric ether freely to head and spine and fanned away till six ounces are used; ice at the same time to arms, wrists, abdomen, over the heart, legs, etc., and, in extreme cases of comatose collapse, ice-cold water into the bowels with ginger and capsicum, but ordinarily moderately cold water with two hundred grains of bromide of potassium.

Cocaine Spray in Epistaxis.

I. A., aged 20, suffering from a severe attack of typhoid, was troubled by frequent epistaxis, and Dr. Francis L. Haynes tells us in the *Therapeutic Gazette* (July 15) that the attacks were invariably relieved by throwing into the nostrils, for a few moments, spray from a two per cent. solution of cocaine. On one occasion, copious bleeding was allowed to persist for three hours, when the spray checked it immediately. Until the patient convalesced, the spray was needed almost daily, and frequently several times a day, but the nurse never allowed more than a few drops of blood to be lost.

Correspondence.

Malarial Hæmaturia.

Eds. Med. and Surg. Reporter:

Seeing an article in your valuable journal by Dr. T. A. Stamps, upon the subject of Malarial Hæmaturia, only awakens my past experience in combating this fearful and much-to-be-dreaded malady. While I like to be brief and practical, like the guest at table, I don't like to drink so much water to get a little coffee—for practical and not theoretical ideas is what the busy practitioner wants.

Now, what is it? Well, in 1873 I commenced the practice in southwest Arkansas, a very sickly, malarious country, and so, as chills were common, I found that this disease was only the result of aggravated chills, or protracted cases of malarial poison. The doctors had never cured a single case, and on one occasion I was invited by one of the prominent physicians, Dr. Tom Roland, of Arkadelphia, Ark., to visit one of these cases. I saw the patient, but in a dying condition, perfectly yellow, the urine bearing the appearance of fresh blood drawn from a vein. I remarked to the old doctor, for he was quite a good unprejudiced one, that I did not mean to be arrogant, and hoping he would not think me so egotistical, I believed I could cure a case, if I could see it in the first stage. "Very good," said the doctor, "you shall have a trial."

It was only a few days when a call came for the doctor, accompanied by a bottle of this blood-like urine. Then said he, "Go and treat this case for me." I was anxious to put my idea to a test, and also, if possible, do some good. When I reached the patient I found incessant vomiting, ropy mucus, with bile, etc. Patient orange color, also conjunctiva, high fever, etc.

Well, now, let us philosophize a little, for the real practice is based upon common sense principles. Here is a system poisoned with an absorption of bile, checking and blockading all the secretions and common emunctories and sewers of the system, if you please, and let us open them up, and help nature throw off the obstruction and assert her normal functions. My plan was this: I ordered twenty-four ears of corn in shock or ear put into a pail of water to a boil, and take this and place it around the patient so as not to burn, and a blanket over him. I had four men to sit one in each corner, and confine the steam and patient, for they are restless and generally wild. I ordered and kept cold water to head and gave patient plenty to drink. What was the result? My patient sweat like a bobtail bull in fly-time, and the perspiration was so charged with bile or its coloring matter that it stained the bed linen its color, and never washed out. What next? I ordered mercurial ointment rubbed on the inside of the thigh, while quinine, capsicum, camphor, and mur. tinct. of iron, I had rubbed all over my patient. I forgot to say, as the bowels are generally very sluggish, that I gave a turpentine enema, which acted well. How was my patient? I returned; saw the old doctor; I said, "My patient is better." "Oh," said he, "it is all a symptom for the worse. He won't get well, you will see." "Well," I said, "the improvement is very encouraging."

I went back, repeated my bath. Patient could then retain anything on stomach a little while. I gave ♏x tinc. aconite in one-half glass of water, teaspoonful every two hours, as I have wonderful faith in this in all fevers, at least in small doses.

Well I cured that year eight out of nine on this same experimental treatment. Suffice it to say it gave me some notoriety, I did a good practice, and seldom lost a pa-

tient. Let all who come in contact with such give my treatment, and report success. The urine is not bloody, but contains cholesterine; dip a white cloth in it you find the yellow copperas dye. Hoping this may prove good, I remain yours respectfully,

L. V. Weathers, M. D.

San Antonio, Texas.

News and Miscellany.

Caught in His Own Trap.

David Ker thus writes in *Harper's Magazine* for May:

"Men will sham any complaint nowadays to avoid their work," said our worthy skipper, as he sat at the head of the breakfast-table on our first day out. "I had a fellow once who pretended to have lamed himself when were about half-way out to Calcutta; and he did it so well that nobody ever suspected him a bit, and one night there was a false alarm of fire, and the way that *lame* man flew up the ladder would have astonished an acrobat."

"Well," said I, "you remember that story of the Irishman who went about Dublin with 'Pity the poor blind' on a board round his neck, and made quite a good trade of it, till at last one of the people who used to give to him met him in a by-street, stepping along like a prize pedestrian.

"'You old humbug,' cried he, 'you see as well as I do.'

"'Sure, thin,' says Paddy, looking down at the 'blind' board that he carried, 'they've hung the wrong board on me to-day by mistake. It's *deaf and dumb* I am.'"

"Well, I once saw something almost as good as that myself," said my right-hand neighbor, Professor T., "when I was on a visit to my friend Dr. L., in the east of France. There was a great conscription going on just then for the Crimean war, and L. had to test the recruits as they came in, to see whether they were fit for service.

"Now among these fellows there was one fine, sturdy Auvergnat, just the stuff for a soldier, if he hadn't unluckily been stone-deaf. So he said, at least, and it certainly appeared to be true, for all the tests that they applied to him couldn't make him give any sign of hearing a bit. *I* fully believed his case to be genuine; but I could see by the twinkle in Dr. L.'s eye that *he* didn't.

"'That'll do, my man,' said L. to him at last, in a low voice. 'You're too deaf to be of any use to us. You can go.'

"Instantly the recruit, forgetting himself in his glee at having got off so easily, sprang toward the door like a cat.

"'Not so fast, my fine fellow,' shouted the recruiting officer; 'if you can hear *that*, you're not too deaf for the army. You're a mighty cunning rogue, but this time we've caught you in your own trap.'"

M. Pasteur.

We take the following interesting account from the *Brit. Med. Jour.*, March 27:

Our Paris correspondent writes: The *Journal d'Alsace* publishes an article, signed by its director, Gustave Fischbach, in favor of a subscription for the Pasteur Institute. M. Pasteur was formerly professor in the Strasbourg Faculty of Sciences; the boy Meister, an Alsatian peasant, was the first patient treated by M. Pasteur. In two days, the amount subscribed has reached 3,301 francs (£128). M. Pasteur has written a charming letter of acknowledgment to Herr Fischbach. The President of the Paris Academy of Medicine announced at the last meeting that the state of the finances had been inquired into, and it was proposed that the Academy contribute £400 to the Pasteur fund: the proposition was unanimously adopted. A telegram from Rome has arrived, announcing that the King has conferred the order of Saints Maurice and Lazare on M. Pasteur. The assembly of M. Pasteur's patients presents a motley aspect; a literary contemporary describes it as follows: Along with fifty French subjects, there is a troop of English children, five Italian peasants shrouded in their woollen cloaks, and nineteen Russians from Smolensk dressed in fur-skins. The Russians have all been badly bitten in the face by a mad wolf. For dog-bites, M. Pasteur inoculates once a day during treatment; but for wolf-bites, which are more serious, the inoculations are made twice a day. The Russian Minister of Public Instruction has asked M. Pasteur if he will receive in his laboratory Russian medical men, to study his method of inoculation for hydrophobia. M. Pasteur has expressed the satisfaction he should feel on welcoming Russian scientists to his laboratory; but at the same time believes that one international establishment suffices for France, Europe, and even North America. M. Pasteur proposes that the international institution should offer every facility for carrying on researches on inoculation of the virus of contagious diseases of both mankind and the lower animals, where scientists from all parts of France and other

countries could pursue their researches. Prince Alexander of Oldenburg has created at St. Petersburg an establishment on a small scale for applying Pasteur's method. Experiments are made on dogs and rabbits before operating on man. Prince Alexander defrays all the expenses of the establishment.

Chlorophyll in Plants.

From an exchange we learn that experiments have been tried by Dr. A. Hansen with the view of determining the amount of chlorophyll in given areas of leaf surface in plants, and so to ascertain the amount necessary to the production of a given weight of starch. The plants he experimented upon were the sunflower, pumpkin, turnip, and tobacco. He isolated chlorophyll by boiling the leaves for a short time in water, and then extracting by means of 96 per cent. alcohol. After saponifying the alcoholic solution, the chlorophyll was extracted by means of alcohol—ether evaporated, dried, and weighed. He found that the amount varied considerably with the species, but the average he obtained was 5.142 grammes to the square meter of surface. Sachs, in his experiments on the pumpkin and sunflower, had previously determined that these plants form about 1.6 grammes of starch per hour per square meter of surface. The amount of chlorophyll, therefore, adequate to the production of 1 gramme of starch per hour is about .2 of a gramme, or one-fifth the weight of the starch. Dr. Hansen also believes that the function of chlorophyll is to act as a carrier of carbon dioxide to the protoplasm of the chlorophyll bodies, and that the real work of assimilation is accomplished by this, and not by the chlorophyll itself.

Equivalent Weights.

The *Therapeutic Gazette* tells us that the following rather good story is related in the *Petit Moniteur de Médecine* for April, 1886:

A doctor, practicing in the country, brought a package of powder in bulk to a woman, of which she was to give to her husband seventy-five grains daily. As she said that she had a pair of scales, but no weights, the physician told her that a one-franc piece (a quarter of a dollar) weighed about the amount which he wished to have given, and that she might therefore give him daily the weight of a franc piece of the powder. Two days afterwards the doctor, to his great astonishment, found his patient dead. The explanation of this mystery was, however, readily reached. It turned out that the woman had no silver piece, and that she thought the equivalent in money, no matter how arranged, would be the proper dose; she therefore, instead of putting the silver coin in the balance, put in twenty-five copper pennies. The result was evident.

To Render Wood Incombustible.

"Invention" describes a new patent for rendering wood incombustible, in which the wood is first well dried, and afterwards impregnated with a solution of about 4 parts by weight of borax and about 3 parts by weight of Epsom salt in about 20 parts by weight of hot water. The impregnated wood is coated with a mixture of hot clay and a sufficient quantity of liquid water-glass to enable the mass to be applied by means of a paint-brush. The wood, having again become dry, is covered with paper or with woven fabric, the latter having likewise been impregnated with the solution. Lastly, the whole is painted over with a mixture of from 30 to 40 parts by weight of sulphate of ammonia, and from 35 to 45 parts by weight of gypsum diluted with a sufficient quantity of water.

A Reasonable Discount for Cash.

A well-known English surgeon recently performed an operation on a little boy. The operation was comparatively trifling. The mother and the father and the little boy were in the surgeon's house just a quarter of an hour. "What is your fee?" said the father. "A hundred guineas," was the reply. The father was startled, and said he had not a hundred guineas. "Oh! then I will take fifty guineas." "But I cannot afford it," said the father; "and had you told me what your charge would be, I would not have come." "Then I will take twenty-five guineas." After a little more delay, the surgeon took ten guineas on account. Clever man that. His principle is to demand all, and take what he can get. He is at all events an adept at trying it on.

The Progress of Chemical Science in Japan.

From the annual report of the Tokio Chemical Society which was recently presented, it appears that the study of chemical science is making rapid progress in Japan. Ten ordinary meetings and one annual meeting were held during the year, at the latter of which an important paper on the "Constitution of some Non-saturated Oxygenous Salts" was read. The society has under-

taken to translate chemical terms into Japanese, and it now possesses a dictionary of the commoner chemical terms in Japanese, English, French, and German. It has also undertaken to establish a system of chemical nomenclature in the Japanese language, of which the nomenclature of elements and of inorganic compounds is already nearly finished.

The Age of Trees.

The *Western Druggist* tells us that the Chief Forester of Prussia denies that trees ever attain the age of a thousand years, as was formerly supposed. His investigations result in placing the extreme age of the pine at 570 years, of the larch at 429, of the oak 410, of the red beech 245 years. The chronicles of Wurtemburg show a certain linden tree at present in existence to be at least 438 years old, but except for the artificial protection it has received it would doubtless long ago have been blown down, as seven of its large branches are now sustained by stone columns, and its trunk is a mere shell, supported internally as well as externally by masonry.

The Malign Influence of the Morphia Habit.

An exchange tells us that a girl was taken before the Paris tribunal charged with stealing a blanket. She pleaded that she was under the influence of another person, and could not help herself. In prison it was found that she was in a hypnotized condition, and acted readily under the commands of others, doing anything that was told her. She was examined by a commission of Charcot, Brouardel, and Mollet, who reported that this state came from the use of morphia, suffering, and hunger; and that these suggestions from others, acting on an unstable nervous organism, greatly deranged by morphia and other causes, rendered her irresponsible for her acts. She was acquitted.

Arsenic in Skin Diseases.

The editor of the *Journal of Cutaneous and Venereal Diseases* is desirous of ascertaining to what extent arsenic is used by American physicians in the treatment of skin diseases, and also the results of their experience as to its therapeutical value. Information upon the following points is requested of every physician who reads this: Are you in the habit of employing arsenic, *generally*, in the treatment of skin diseases? In what diseases of the skin have you found arsenic of superior value to other remedies? What ill effects, if any, have you observed from its use? What preparation of the drug do you prefer, and in what doses do you employ it? Address, Editor of the *Journal of Cutaneous and Venereal Diseases*, 66 West 40th street, New York.

Bay Rum in the West Indies.

Mr. R. Bergter writes from Curaçao to a German pharmaceutical journal that bay rum is very largely used there to add to water for washing purposes. The foreign steamers calling at the islands are in the habit of regularly taking a case of bay rum for use on board. But for this purpose the bay rum must be of the best quality, distilled from the leaf. Saint Thomas produces the best bay rum, and also essence, which, however, is much less efficacious. It should be noted that in the West Indies all sugar spirit of a certain strength, generally 21° Cartier, is called "rum." Venezuela has latterly commenced to produce bay rum of very fair quality, but the production there is handicapped by almost prohibitive duties.

Indestructible Paste for Closing Letters.

Letters or envelopes which it is desired to protect against unauthorized opening (by moistening the pasted portion), may be securely sealed by using a solution of oxide of copper in ammonia as paste. This liquid has the faculty of dissolving cellulose. When applied to the paper it dissolves the cellulose on the surface, and on drying the two partially dissolved surfaces adhere indissolubly together. The same thing may be accomplished by using water-glass (silicate of soda or potassa). In this case the chemical action is different, but when it is completed, the pasted surfaces cohere as permanently as in the preceding case.

Sponge Raising.

Sponge raising in the waters of Long Island Sound is likely to become an important industry in the near future. It is believed that sponges of ordinary quality may be grown at a profit. The frequency with which several varieties of native sponges are found has induced some scientific men to plant young sponges from Florida waters off Stratford Point, where there is a long reef of submerged rocks of a nature suitable for sponge growing. The transplanted sponges have lived and flourished rapidly, growing to the size used in commerce.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE THREE WEEKS ENDED JULY 17, 1886.

White, J. H., assistant surgeon. Granted leave of absence for thirty days, July 12, 1886.

Pettus, W. J., assistant surgeon. When relieved at Charleston, S. C., to proceed to Savannah, Ga., for temporary duty, July 9, 1886.

Inebriety and Insanity.

The *Quarterly Journal of Inebriety* says that there are over 17,000 inmates in the alms-houses of New York State. Over 100,000 persons are in asylums, and registered as out-door poor. Over half this number are inebriates, or children of inebriates. Except the insane and idiotic, they are all regarded as sane, and as persons who have voluntarily brought this condition upon themselves, and, as such, subjects of punishment and prosecution.

An Opening for Physicians in India.

According to a letter in an Austrian journal, a most promising field for medical practice exists in India, especially in the inland parts of the peninsula. There is plenty of sickness, and physicians receive large fees. A knowledge of the language, sufficient for all practical purposes, is readily acquired, and beyond that, the writer states, nothing is needed for the acquisition of a large practice and a handsome income.

Items.

—Not very good days are these for hurry or worry or fret, or hard bodily work, or exhausting labor in hot rooms.

—Surgeon-General Robert Murray, of the U. S. Army, will be 62 years of age in August of the present year, when he will be placed on the retired list.

—"Cases for the coroner" are plenty enough without adding to the number by excesses in eating or drinking, or indiscretions of any sort, this hot weather.

—In Vienna, Austria, a local committee of twenty-five members has been formed for facilitating arrangements for attending the Ninth International Medical Congress in Washington, 1887.

—Some Poles in Toledo came near creating a riot because the meat-inspector attempted to prevent them from eating the meat of a cow which had died of splenic fever.

—Unless you are obliged to be in the sun on such blazing days as the last two or three, keep shady. If you must be so exposed, try to have the lightest sort of head-gear—straw-hat preferable, and in that have a moist handkerchief.

—The *American Lancet* says that "*an infinitesimal shrew-mouse squeaklet of a mediker*" is the latest term of reproach applied to a medical man in the secular press by another medical man. Unable ourselves to understand its meaning, we present it to our readers as a puzzle.

—Lady (to applicant)—"What wages will you expect as nurse?"

Applicant—"How ould is the babby, mum?"

Lady—"Seven months."

Applicant—"Widout laudanum, mum, two dollars an' a half a wake; wid laudanum, two dollars."

OBITUARY NOTICE.

George Sutton, M. D.

Dr. George Sutton, of Aurora, Indiana, died at his home in that city, on June 13, 1886, aged 74 years. He was born in London, England, June 16, 1812, and emigrated with his parents to this country in 1819. He graduated from the Medical College of Ohio, in 1836, and shortly afterwards commenced the practice of medicine at Aurora, Indiana, where he remained ever since. He furnished many important papers to the Indiana State Medical Society, of which he was an honored member, being elected its president in 1869. His writings on cholera, trichina, parasites, reduction of dislocation of the hip-joint, and epidemics of southeastern Indiana, are replete with valuable and original ideas. Dr. Sutton was a scientist, and the study of nature to him was ever a great source of pleasure; and although engaged in active practice, he devoted a portion of his time to geology, meteorology, and archæology. He made collections of fossils and geological specimens, forming a cabinet of many thousand specimens unsurpassed by any in that portion of the State. His articles on "Glacial Deposits," "Formation of Storms," and the "Cause of the Great Floods in the Ohio Valley," were extensively copied in the scientific journals of the day.

At the time of his death he was an active member of several national and state societies, both medical and scientific, as well as an honorary member of many others.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

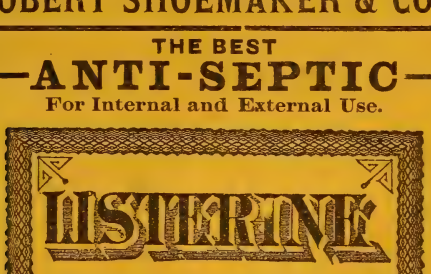
THE BEST

—ANTI-SEPTIC—

For Internal and External Use.



FORMULA.—Listerine is the essential Antiseptic constituent of Thyme, Eucalyptus Baptisia, Gaultheria, and Mentha Arvensis in combination. Each fluid drachm also contains two grains of refined and purified Benzoboracic Acid.

ANTISEPTIC, PROPHYLACTIC, DISINFECTANT, NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC, AGREEABLE, STRICTLY PROFESSIONAL and SCIENTIFIC.

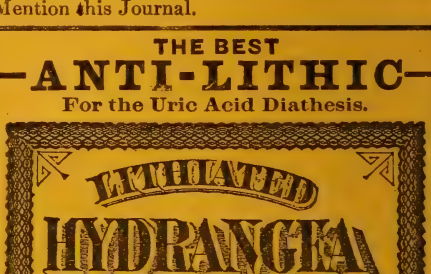
LISTERINE comes nearer the ideal Antiseptic than any preparation now before the Medical World.

Send for New Formula Book and General Reports, establishing its value externally in SURGERY, OBSTETRICS, GYNECOLOGY, LEUCORRHŒA, GONORRHŒA, and all MUCOUS MEMBRANE DISEASES; internally in TYPHOID and other FEVERS, ZYMOTIC DISEASES, DIPHTHERIA, SCARLET FEVER, DYSPEPSIA, DYSENTERY, DIARRHŒA, all forms of CHOLERA, etc., and as a general PROPHYLACTIC

THE BEST

—ANTI-LITHIC—

For the Uric Acid Diathesis.



FORMULA.—Each fluid drachm of "Lithiated Hydrangea" represents thirty grs. of Fresh Hydrangea, and three grs. of Chemically Pure Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

KIDNEY-ALTERATIVE AND ANTI-LITHIC, RELIABLE, UNIFORM, AND DEFINITE.

The solution and elimination of an excess of uric acid and urates is best attained by an intelligent combination of certain forms of Lithia and a Kidney Alterative.

The ascertained value of Hydrangea in Calculous Complaints and Abnormal Conditions of the Kidneys through the earlier reports of Drs. Atlee, Horsley, Monkur, Butler, and others, and the well known utility of Lithia in the diseases of the uric acid diathesis, AT ONCE justified the therapeutic claims for Lambert's Lithiated Hydrangea when first announced to the Medical Profession, and it is now regarded by Physicians generally as the best and most soothing Kidney Alterative and Anti-lithic Agent yet known in the treatment of URINARY CALCULUS, GOUT, RHEUMATISM, BRIGHT'S DISEASE, DIABETES, CYSTITIS, HÆMATURIA, ALBUMINURIA, and Vesical Irritations generally.

Lecture.

ON HYGIENIC THERAPEUTICS.

A CLINICAL LECTURE BY DR. DUJARDIN-BEAUMETZ,

Member of the Academy of Medicine, Physician to the Cochin Hospital, Paris, France.

Gentlemen: In the earliest period of human society man had only a few hygienic means at his command with which to combat disease, and the practice of medicine consisted only in the administration of certain drinks, in the application of heat and frictions; for the primitive savage, ignorant of the medicinal properties of the plants around him, was unable to make any use of them, and such therapeutics as he had were of a hygienic character. We find evidence of this in the customs of certain barbarous tribes who still live pretty much as did the primitive man of the stone age.

My friend, Dr. Hyades, who has passed a year among the natives of Terra del Fuego, has given us a graphic account of their mode of treating diseases, from which we see that apart from rubbings and vapor baths, administered by heating water under blankets with which the patient is surrounded, and cold baths which are always given to every lying-in-woman immediately after her confinement, these people bestow almost no treatment on their sick. They might, indeed, utilize certain medicinal plants which grow in that country, but they do not use them, being ignorant of their curative virtue. Only at the moment of the death agony they compassionately smother the dying patient to terminate his sufferings.

In proportion as man rises in the scale of civilization, we witness the advancement of hygienic and therapeutic means. We must go back to the ancient Hindoos in order to find the first rudiments of hygienic therapeutics, and among this people the treatment of the sick has for ages been a religious duty.

It is in the sacred books of India, the Rig Vedas, and the Code of Manou, that we find the precepts of this religious hygiene. The protecting deities of medicine, the Aswins, preside over everything that pertains to health. It is to them that the sick apply for relief, and to show you the important role attributed to air and water in therapeutics, I can not do better than cite certain passages from a sacred hymn of the Rig Vegas:

"O God, man staggers in his weakness—direct and help him; man commits grievous faults for which thou dost punish him—restore him to life.

"Two winds blow: one from the sea, the other from the main land. How the blast of the one revives, and how the other prostrates us!

"O wind, bring the remedy; O wind, dissipate the evil. Thou possessest all medicinal virtues; thou hast been sent from the gods.

"The wind speaks: 'I come to thee with health and happiness, I bring thee strength and beauty, I sweep away disease.'

"The waters are salutary, the waters remove sickness: in them is every kind of remedial power; may they give thee health."

Apart from these precepts of hygiene, the therapeutics of the Hindoos is simply a therapeutics of prayers and offerings addressed to the gods. This kind of primitive medicine offers nothing that is definite, and is rather fetichism than true art.

There was another ancient people that

gave to hygiene a much more poweful impulsion, while still preserving its religious character: I allude to the Jews, who found in the tables of the Pentateuch hygienic precepts which are just as applicable to our day. These laws regulated alimentation, the care of the person, ventilation, etc., and man was clean or unclean according as he religiously observed or neglected these precepts.

Egypt adopted and perpetuated the Hindoo practice, and instituted sacerdotal medicine, which was composed exclusively of hygienic observances, consisting almost entirely in baths, gymnastics, massage, and bodily exercise; if you add the usage of a few purgatives, you will have the sum of the means which they employed in the treatment of the sick. This aggregate of hygienic prescriptions was directed by laws and decrees which fixed the occasions for their administration.

But the nation which carried farther than any other these precepts of hygiene, forming of them a complete system, was the Grecian. This race was impelled in this direction by its love for beauty in all its forms: a passion which enabled the Greeks to create those master-pieces of art which we moderns have never been able to equal, and which have been the delight of the past, as they will be of future generations.

To show the intimate union of medicine with hygiene, the Greeks in their poetical mythology made Hygeia, the goddess of health, the daughter or wife of Esculapius. Moreover the pupil of the centaur Chiron (Esculapius) had at his command no means but such as were hygienic, and the priests who served at his altars at Cos and Epidaurus practiced only hygienic therapeutics.

The temples of Esculapius, placed near the sea-shore in the most healthy situations, surrounded with sacred trees, and erected in the neighborhood of natural or mineral springs, offered to the numerous patients who flocked there for the recovery of their health, all those desirable hygienic conditions which we to-day look for at our sanitaria.

Reclining on the steps of the temple, subjected to a special alimentary regimen, and favorably influenced from a moral point of view by the idea of the divinity present, and by the numerous votive offerings which, being hung on the walls of the temple, were a demonstration of the innumerable cures wrought in this place, the patients found themselves in the best possible conditions to obtain restoration.

These hygienic means were the only ones which the followers of Esculapius possessed. They barely supplemented them with the usage of certain simple herbs, such as hellebore; hygienic therapeutics, as we have seen, constituted the sum of their resources.

Then the Esculapians were divided into two groups; one remained attached to the temple, preserving their sacerdotal character —these were the sacred Esculapians; the others abandoned the temples and became the lay Esculapians, who traveled over the various parts of Greece and the East, and received, by reason of their journeyings, the name of *Periodeutes*. It is to this last group that the founder of medicine, the divine Hippocrates, belongs.

The contemporary of Socrates and all the illustrious men of the age of Pericles, Hippocrates was the first to establish the bases of the dietetic regimen of diseases, and in his treatises of medicine, he has given two chapters which were for many ages the sole guide of the physician in the hygienic treatment of disease.

In his treatise on "Airs, Waters, and Places," Hippocrates shows the importance he attaches to hygiene. These are his words: "Whoever would have a thorough knowledge of medicine, must not be ignorant of the subject of which I here treat."

But it is especially in the book entitled "Regimen in Diseases," that Hippocrates insists on hygienic therapeutics. He passes in review the different foods, dwells on the advantages and disadvantages of wine, and considers white wine as an excellent diuretic. According to him, garlic is a stimulant and acts on the kidneys; cheese is heating; lentils are astringent. As for the meats, fresh pork is hurtful, and he advises that this meat should be eaten cold. With regard to bread, he says that that which is poorly cooked gives rise to flatulence, while warm bread is of difficult digestion. Lastly, the originator of the use of baths in acute diseases, Hippocrates, counsels the treatment of inflammations of the lungs by warm fomentations. You will find, moreover, scattered all through his writings innumerable paragraphs referring to hygienic therapeutics.

For a long time the successors of Hippocrates followed the teachings of their master, but by degrees changes were introduced; for rational hygiene, empirical practices more or less absurd were substituted, and these attained their acme in the school of Alexandria. There resulted from this gross empiricism such abuses that there was soon a return to the doctrine of Hippocrates, and the most zealous reformer in this direction was Asclepiades, the Bithynian.

Asclepiades discarded all useless and dangerous drugs. He taught that sick persons should be sustained and restored to health by hygienic means alone, and especially by exercise. He recommended that particular attention should be bestowed upon the different emunctories of the economy, and especially the skin.

The Romans borrowed from Greece their knowledge of the arts and of medicine; and it may be affirmed that there were hardly any Roman physicians—almost all were Grecian, and the great majority came from the school of Alexandria. These medical men added but little to the doctrine of Hippocrates.

Celsus, in his fine treatise *De Re Medica*, devotes a long chapter to hygiene, the first in this work. This first book takes up the hygienic precepts which robust persons must follow in order to preserve their health; then in other chapters he traces the rules of diet in summer and in autumn, and shows that these rules vary, not only with the season of the year, but also with the temperament and age of the subject.

In the same age, *i. e.*, about the first century of our era, during the reign of Augustus, appeared the first indications of a hygienic practice which, resumed in our times, is one of the most powerful means of hygienic therapeutics; I refer to the employment of cold water in the treatment of acute diseases. It was Antonius Musa who was the first to apply this agency to cases of sickness, and by the use of cold water internally and externally he cured the Emperor Augustus.

Euphorbius, brother of Musa, continued the cold water treatment, but it was Charmis, of Marseilles, who practiced medicine in Rome at the same period, who carried the farthest the method of cold baths as applied to the treatment of diseases; and Pliny has mentioned the fact that it was a common thing for aged Roman Senators, obedient to the ordinances of Charmis, to shiver from the cold in the baths prescribed by this physician.

Then came Galen, who was destined to sum up in his writings the entire medical lore of antiquity, and serve as an authority to the generations that were to follow. In his works he does not omit hygienic therapeutics, and in his celebrated chapter on the *Care of the Health*, he shows the influence of the quality of foods, of exercise, and of rest, of waking, and of sleeping, on the progress of diseases. Only these hygienic precepts are buried in the midst of so much empirical rubbish that their value is considerably lessened.

From this moment, which may be considered as the declining point of Greek medicine, progress ceased to be made, and deep night settled over everything which pertained to rational therapeutics. The barbarians invaded Italy and the entire Roman empire, and that religion which was to conduct modern nations to a higher civilization —Christianity— directed medical practice into new paths, in which everything relating to hygiene was abandoned.

The people of antiquity, admiring physical beauty, were wont to put in usage all hygienic measures which were calculated to inspire strength and grace of person, and their philosophic, religious and social ideal was summed up in this one sentence: "The mind of a sage in the body of an athlete."

Christianity, on the other hand, addressing itself exclusively to the soul, in its fervid mysticism could but despise all attention bestowed on the body, that fleshly envelope and clog of the soul.

So firm and irradicable were these tendencies to neglect the body as being the baser part, to be treated with contempt and kept in subjection, that even at the present day there are religious communities distinguished by their neglect of the person and of the ordinary cares of hygiene.

The Arabs, who aimed to represent the traditional teachings of Galen, added but little to the hygienic precepts of the physician of Pergamos, and leaving to one side everything pertaining to hygienic therapeutics, they insisted much more on the employment of pharmaceutical agents, and we have to come down to A. D. 1100 before we find in the midst of this Middle Age chaos a few physicians attempting to bring medicine back to its original rational basis, and inculcating the practice of hygiene as a means of cure. This reformation was confined to the school of Salernum.

Situated on the borders of the Gulf of Salernum, this city, bearing the name of its gulf, was conquered by those hardy Normans who, returning from the Crusades under the leadership of Robert Guiscard, took possession of Apulia and Calabria. Here was founded, under the direction of John of Milan, a school of medicine which long possessed a great repute. This school was constituted by a strange medley of ecclesiastics, physicians, and female doctors, whose names history has preserved, and among which we find mentioned Trotula, Abdulla, Mercurias. But that which above all gave celebrity

to this school of Salernum is the work in leonine verses to which various names have been given, such as: "*Regimen of Health of Salernum*," "*Flowers of Medicine*," "*Medicine of Salernum*."

(*To be continued.*)

COMMUNICATIONS.

ON THE PATHOLOGY OF SURGICAL INFECTION AND THE VALUE OF ANTISEPSIS.

BY A. H. P. LEUF, M. D.,

Pathologist to St. Mary's Hospital and to the Hospital for Nervous and Mental Disease, Brooklyn, N. Y.

The subject of which it is my intention to treat this evening is so replete with food for thought and discussion that it seems endless. It also is inseparably connected with general infection, so that a discussion of the one necessarily involves a consideration of the other. No sharp lines can be drawn between the two. While it is my intention to treat the selected subject thoroughly, an effort will be made to refrain from all unnecessary mention of extraneous matter. Exception will be taken against the now so prevalent extreme methods of antisepsis during operation and subsequent thereto.

Personal experience in the frequent handling of dead bodies in various stages of decomposition, and dead of all kinds of disease, in connection with operative surgery, privileges me to have a say.

In this day of specialization also, when everything is apt to be viewed from only one standpoint by each individual, and this standpoint depending upon the special work the viewer is engaged in, it behooves some one having a more general interest in our work to look upon everything from all possible points of view for the purpose of establishing relative values. The neurologist, for instance, will claim every pain or ache as coming exclusively within his particular domain, while the operative surgeon will insist upon its being permanently curable only by instrumental interference.

Recognizing the scope and depth of this subject, the limited time allotted for its consideration, and being desirous of treating it fully and yet concisely, an effort will be made to arrange it in a systematic manner.

It is the object of this paper to take up the healing of wounds, the methods of so-called surgical infection, the cause of excessive surgical fever, the prevention of this condition, and the value of the general application of the germ theory and its logical outcome, antisepsis.

The prevailing fashion of unnecessarily lengthening a paper with a long bibliographical list will be ignored, and only such few references made as seem advisable. Advantage is hereby taken of this opportunity to again call attention to that most remarkable work of its kind—*The Index Medicus*. It should replace all those needless tails of reference that we find tied to papers of all grades. More numerous and complete references can be found there of the current literature on this subject than any single individual could otherwise collate.

Wounds heal essentially but in two ways. These may be and by some are denominated primary and secondary. The first occurs without the formation of pus, and the second is accompanied by suppuration. In the latter we have granulations and granulation tissue, while in the former healing takes place without granulations, although the process of repair results in an identical tissue.* Repair in all instances is effected only by the cell. The participation of the blood-vessels in this process is secondary, and their secondary function is to nourish the cells that are doing the work, thus continuing proliferation and growth.

All living tissues have common and special power of reaction. The common reactions are those of mere vitality, while the special reactions are the result of the performance of duties not essential to life. Thus every cell does the common work of maintaining itself. In addition to this, cells do their own special work as living individuals; for instance, the ordinary connective tissue cells, which form the framework that supports the essential elements of an organ and its nutrient vessels and nerves; or the cerebral cells, which preside over the volitions of the body and the associations of its various workings; while the liver, kidney, pancre-

*By suppuration I mean any fluid exudation from a wound's surface containing multinuclear cells—leucocytes. The so-called "union by granulation without suppuration" of the antisepticists is only apparently true. The object of suppuration is the protection of the granulating surface from extrinsic influences, particularly over-dryness and hardening of the surface. In proportion as there is diminished chance of evaporation there may be lessened pus formation, and more especially is this true when the surface is well protected by sponge or other suitable material, and dressings that are more or less sealed. This is true in very much the same way that it is that the amount of callus in a fracture depends largely upon the irritation of the broken ends of the bone and their displacement. I am well aware that this view of suppuration may seem new, but be that as it may, it is the sense in which the term is employed throughout the paper. Any exudate from a granulating surface will be found to contain leucocytes, and therefore is pus. It may only be detectable by its effects in preventing dryness and hardening of the surface. There is no such thing in reality as "healing by granulation without suppuration."

atic, and red and white blood cells are still different. It is by their common reactions that cells or tissues overcome disturbances. Let there be a breach of continuity in any of the tissues, and the steps by which the injury is overcome, or attempted to be overcome, are essentially the same in all. Perturbing influences, whether slow or sudden, will have definite effects upon all structures, but often as different as are those structures themselves. A wound of the brain and one of the skin heal essentially in the same way, but the manifestations and results are not alike. In the same manner a similar disturbing cause will affect differently various people or groups of people.

The connective tissue cell is the essential element of the body's framework. It binds together all our different parts. Whenever there is a breach of continuity, it is the *special* duty of this cell to make the necessary repair in restoring continuity. This is but in accordance with all physiological processes, as continuity depends upon the connective tissue, and when continuity is severed, this tissue is injured. Those elements which happen to be enjoying the support of this structure at the seat of the wound, have no connective function, they do not aid in the repair, they are injured and they die.

Repair is effected by proliferation. All the lower tissues proliferate when sufficiently disturbed, while the higher tissues never do. In inflammation the higher tissues perish, while the lower tissues increase. These lower tissues are embraced by the great connective tissue group. If higher structures proliferated, a man with nephritis or hepatitis ought to get larger and better kidneys and liver on that very account, but the truth is that the framework of the organ (the lower or connective tissue) is increased, while the higher, the essential secretory structure, is diminished—destroyed.

In all solutions of continuity, therefore, there is increased life and activity, proliferation of the connective tissue on the one hand, and diminished life and activity, death of the special cells, on the other. The dead elements are removed by absorption or by ecrysis. If small, as in a simple incised wound, absorption is the rule. If large, as in a lacerated or contused wound, ecrysis predominates, and we have a slough or gangrene. There may be, and often is, absorption without ecrysis, but never the latter without the former.

Proliferation is reduced to a minimum in primary union, and is excessive in healing by granulations. The former it is almost always our object to attain. The latter may conveniently be divided into three stages, as will appear. When a wound is just made there is a transudation of blood from its surface, and this is soon accompanied by a flow of lymph. A variable time after the trauma (depending upon its site, extent, and the patient's condition) there is added a flow of serum, and the hemorrhage gradually subsides, until eventually there is no longer any transudation from the surface of the wound. It begins to take on a glazed appearance, due to the coagulation of albuminous matter, variously known as coagulable lymph, plastic lymph, plastic exudate, etc. Somewhat in the same way as microbes are developed from gelatine and animal broth (nutritive gelatine), we find the superficial connective tissue cells of the wound's surface increase in size and number. The glazing of the surface takes the place of the microbist's gelatine, and the adjoining blood vessels represent the animal broth. The wounded connective tissue cells begin the reparative process. The increasing cells push forward like an advancing army, and the blood vessels throw out closely following loops in the same way that the food supply follows a body of soldiers—their functions are similar.* These loops, covered with cells, form granulations. Cell formation is so rapid that many are thrown off with modified serum to form the pus that covers the granulations, and protects them from dryness and other disturbing influences.

The three stages into which the healing of an open wound may be divided are—

1. The period extending from the reception of the injury to the glazing of the wound.

2. The time between the glazing of the wound and the formation of granulations and pus.

3. From the formation of pus to the end of repair.

The healing of wounds is retarded by two sets of causes—local and constitutional.

The local causes may be said to consist of 1st, Anything that will prevent perfect coaptation; 2d, anything that will reduce the local tonicity; and 3d, all sufficiently irri-

*I arrange myself by the side of those who do not believe the migration of leucocytes through the vessel walls to be essential to the inflammatory process—diapedesis—because of repeated failures to observe it after the most careful and persevering observance of an active inflammatory field. What I have seen appeared to be a proliferation of the vessel wall, either inwards or outwards, or both conjointly, and this agrees with Prof. Daniel Ayres' views on this subject. Still, I do not wish to be understood as denying the possibility of diapedesis, and the probability of its inconstant and infrequent occurrence. It seems to me most proper to define inflammation as increased cellular metabolism, with a failure to remove all or a part of the exudate.

tant foreign bodies. The first includes everything that separates the edges of the cut surfaces, and these may be large solid foreign bodies, blood, lymph, serum, water, air, gas, and drains of all kinds, as tube, horse-hair, or silk. The second comprises devitalizing or benumbing fluids and gases, and even a too free and continuous supply of water. The third consists of all kinds of irritating substances.

The constitutional causes are readily divided into nervous, muscular, vascular, and nutritive. General neurasthenia, in the broadest sense of the word, whether it be due to heredity, some chronic or acute disorder, or to anæsthesia, will materially retard or altogether prevent repair, if not properly and promptly counteracted. Lack of promptness may, and occasionally does, involve a loss of life, in consequence of the drain upon the vitality of the patient in ineffectual efforts at union. A flabby muscular apparatus will often, in spite of a fair nervous tonicity, be a barrier to typical repair, causing delay and sometimes failure. Vascular disturbances, by directly modifying local nutrition, interfere with the healthy healing of a wound as insufficient food supply diminishes the effectiveness of individuals who have to perform a given work within a specific period. General nutritive disturbances, as impairment of the functions of the stomach, liver, or kidneys, retard or prevent primary union, and sometimes even normal granulation, by diminishing the general vitality or resisting power.

Elevation of temperature a few degrees above the normal standard is called fever. Such elevation, however, is as normal in some pathological conditions as is the standard in health. Various affections have different thermic elevations peculiar to themselves. The reactionary rise of body heat after hemorrhage or injury is normal under the circumstances by which it is caused. That either general or local irritation will cause such a rise is beyond question. Even excessive anger runs the mercury up the scale.

Most foreign bodies irritate. Dead animal matter is a foreign body. It becomes particularly obnoxious while in process of decomposition. The dead elements on the surface of a wound between the connective tissue meshes, therefore, are foreign bodies, if not quickly absorbed, and produce a detrimental effect. The normal bodily temperature is most favorable to rapid putrefaction, and hence to rapidly converting its own dead tissues into sources of irritation. This is more especially true of lacerated wounds for self-evident reasons.

Many local irritations produce general disturbances. Increased activity of the cerebral cells, as in mental concentration, sufficiently perverts the metabolism of the whole body to elevate the temperature several degrees. A simple neuralgia due to neuritis will have its marked effect upon the body. Likewise a common felon. The same may be said of the painful recovery from an over-worked muscle. Many of these bodily disturbances are etiological factors in elevated temperature—fever.

Nervous excitations not appreciable by the mind cause reflex disturbances. As an example, take the gravid uterus and its accompanying emesis. Peripheral nervous irritation may be caused by a nerve being compressed, or under tension (stretched), or in contact with some irritant. An abscess in a dense tissue produces greater disturbances than one located in a very yielding structure. This is because in the former instance the local disturbance of the blood and lymph vessels and the nerves is greater than in the latter. An abscess grows, especially when it is encapsulated from the inner side of its wall. Surrounding structures are pushed aside. All intervening vessels and nerves are disturbed. The denser the tissue and the greater the abscess, the greater is the effect upon the body. Take, for instance, the general effect of a periostitis with effusion of pus between the bone and membrane. Here we have two very unyielding structures and a marked constitutional effect. Again, take for example the constitutional effect of congestions or inflammations of the tonsils or mammæ. From this it is safe to say that—

Those tissues which have the richest nerve supply and the densest consistence, as a rule, give rise to the most marked constitutional disturbance when congested or inflamed.

Hilton* has done perhaps more than any other single individual to demonstrate and emphasize the influence upon the body, as well as diagnostic importance, of pain, and the great therapeutic value of rest. Gamgee also deserves credit for valuable work of the same kind. John Hilton made elaborate dissections to trace out the finer nervous ramifications, and compared them with the clinical facts of his surgical experience. His investigations were thorough and far-reaching. He was one of the first to show a definite relation in many instances between thermal elevation and nervous irritation. He also proved that great attention was due to

*His remarkable work on the "Diagnostic Value of Pain, and Therapeutic Value of Rest," is one that no scientific physician can afford to neglect to read and study.

the nervous system, both general and local, in the repair of tissue, and that, too, whether or not the air was made a factor by contact with the lesion. He firmly fixed the one great fact, that the more perfect, absolute, and continuous the rest of an injured part, the more favorable were the conditions of repair, and the greater certainty was there of complete, rapid, and satisfactory recovery. Rest has such great therapeutic power because it results in a comparative increase of tonicity by enabling all the forces operating at the seat of injury to concentrate themselves upon the process of repair alone.

A bleeding surface does not absorb. A surface exuding plasma or serum does not absorb. A cover or envelope of coagulated albumen prevents absorption by the surface underneath. A wound, from the time of its inception until its proper closure, is under these varying conditions at different times. At first there is hemorrhage, then an exudation of plasma and lymph, which is subsequently followed by the coagulation of the albuminous constituents of these fluids. During this time absorption is impossible. It does not occur. When the wound is covered with this coagulated layer, it is said to be glazed. When a wound is properly glazed, there is no longer any exudate.* Given a wound in this condition, and free from irritant material, with perfectly coaptated surfaces, and their constant maintenance in this relation, and the result will be primary union. If such surfaces are approximated before glazing is complete, there may be, and as a rule is, still a little oozing of fluid, consisting of blood, plasma, lymph, or all. Given a wound with surfaces approximated, but imperfectly glazed, and gradually a foreign body, the exuding fluid, insinuates itself between the surfaces, separates them, irritates them and the subjacent cells, primary union becomes impossible, and if the tension becomes sufficient or the fluid undergoes chemical changes and thus becomes sufficiently irritant, a general disturbance of the whole body with a rise of temperature is the inevitable outcome. This a great many misname septic infection.†

Glazing requires a variable period. It varies at different ages, in different individuals of the same age, and in the same individual under different circumstances. Glazing depends upon the tonicity of the wound, and this in turn depends upon the local and general conditions already indicated, or is diminished, or destroyed, by the cause above cited.

A cause of atonicity of wounds now exists, and will remain with us, that our predecessors, up to the earlier half of this century, did not have to contend against. It is not appreciated at the present day except by a few. Attention was recently called to it by one of our most reliable surgical authorities —an unimpeachable observer. He saw the steady inroads that this cause was making, in marring the success of those surgeons who, previous to its advent, seldom met with failure. Prevailing methods, previously satisfactory, became unpopular, and were abandoned. Primary union was becoming a thing of the past. Surgeons all over were resorting to the open treatment of wounds—union with suppuration. It was noticed, but not explained, that wounds that were gently handled and left to themselves for open treatment, and on second thought, at the end of half a day or a day, were dressed for the purpose of obtaining primary union, resulted in union without suppuration more frequently than those that were dressed for this purpose immediately after the operation or injury. Few men, if any, at first saw any relation between the advent of anæsthesia and the proportionate failure of primary union, and it seems that those who did considered it only an unaccountable coincidence. Hamilton* dwells especially upon the retardation of glazing produced by the use of anæsthetics. He appears to be the first to have laid much stress upon this important point. It is directly due to local atonicity, and this in turn is caused by the general flaccidity induced by etherization or analogous conditions.

The retraction of cut tissues of an anæsthetized patient is not as great as those of one who is conscious. Operations upon paralyzed limbs do not succeed as well as those upon extremities that are not paralyzed. This difference is best observed in hemiplegics who have both sides injured. Careful surgeons have a well founded temerity

* By "glazing," I do not necessarily wish to be understood as meaning an albuminous coagulate sufficiently thick to be easily appreciated by the naked eye; but what I do intend is the cessation of exudation, with relative dryness and more or less gloss of the surface.

† For the sake of clearness it is perhaps well to state that it is not intended in this paper to use the term 'primary union" as synonym us with "primary adhesion." The idea expressed by the latter term is a fallacy, as it supposes that two normal surfaces can adhere and remain united without the inflammatory process that inevitably accompanies trauma. By "primary union" I mean a union which results without suppuration or surface granulation, and which it is not safe to disturb inside of several days, and which even after that time may be re-severed without very much effect. This is the most advantageous union that can be attained, and its rapid perfection in suitable persons has led to the misconception—"primary adhesion,"

* The Art of Primary Union—N. Y. Med. Record, January 2, 1886.

about operating upon enervated structures.

The large failure of primary union after the advent of anæsthetics as compared with previous successes depended upon the diminution of tonicity produced by these agents. This mode of repair more often succeeded in those instances where the dressing of the wound was postponed for many hours than in those where such dressing was immediately applied, because glazing was only completed after many hours and the comparatively immediate closure of the wound was premature in the great majority of cases. How this objection was overcome, and what it led to, will be considered further on.

We next pass from the first stage of the process of repair to the second, extending up to the formation of pus and granulations. Given a perfectly glazed wound properly dressed, and primary union should be the inevitable result. Such a wound is inaccessible to extraneous matter likely to do harm. If properly cared for, the danger, if any, is intrinsic and depends upon the patient's general condition. Given, however, a wound that is bound to suppurate, I mean one that it is designed to allow to heal by granulation, and the second period becomes a field for speculation, and to this I shall recur.

The third and last period of the wound, the suppurative stage, is devoid of danger or risk, except from the effects of a mechanical or chemical character, such as blows, cuts, and corrosives. Granulation tissue, as previously indicated, consists of new blood vessels and cells. Lymphatics it has none. Neither is it possessed of nerves. *It does not absorb.* That this is a fact has been long ago demonstrated in an experimental way by Billroth* and others. But experimentation is not at all necessary. The practice of surgery is full of demonstrations. A contused and lacerated wound loses part of its tissue by the interference with the local blood supply, due to the injury done the blood vessels in the immediate vicinity. The extent of the slough cannot be ascertained until it is separating from the adjacent healthy living structures. These sloughs, despite their offensive character, view them any way we please, do not cause septicæmia and pyæmia. They are putrescent masses of animal matter, but do no harm except to delay union until they are thrown off. The same thing on a larger scale is seen in gangrene of the extremities and the spontaneous amputations that are the result. When these patients die, it is not from excessive fever, but from the strain upon the nervous system and the drain upon their nutritive resources. Treat these cases as you please locally, and the temperature remains above the normal, unless constitutional remedies are administered, or the excess of heat is carried off by artificial means, such as cold applications, as quickly, or even more rapidly, than it is formed.

The following may be considered a logical deduction from the facts thus far enumerated: *So long as there is any transudation from a wound there is no absorption by that wound.* It therefore follows that as there is transudation of blood, plasma and serum from the wound until glazing is completed, and as there is transudation from the wound of pus from the time granulations are formed until repair is completed, absorption does not, can not, occur during the first and third stages of repair. Of the intermediate stage more will be said below.

We all are aware that a number of patients under like environments and with similar injuries, together in one ward, will fare differently. The results will often be entirely out of all proportion to the kinds of traumatisms. A major amputation will survive with a clear history, while a minor injury or amputation in the adjoining bed will be the only source of worry in the ward to a house and visiting staff, until death puts an end to the suspense. Why is this? Both injuries may have been received under the same conditions, in fact may be due to the same cause and have occurred in the same place; both patients may appear alike in every way appreciable to our senses; both may receive the same care by the same persons; both have similar requirements and are served alike; yet why does one perish and the other recover? This is not a question of infection, although some would have it so. Surgical practice, especially military surgery, is replete with instances when wards filled with injured of all kinds were swept by an epidemic, so to speak, of hospital gangrene; and how is it that a certain proportion of the injured in these same wards, sandwiched between the foulest cases, not only survived, but never had a bad symptom? This is not a question of infection. The prejudice against ligaturing veins became trite and was overcome by original men. To-day veins, the largest that are accessible, are tied. The prejudice against this practice feared pyæmia from such a procedure, because the resulting phlebitis would throw pus into the circulating blood, cause excessive fever, metastatic abscesses—pyæmia. It does not. This, also, is not a question of infection. When occasionally a patient with a ligated vein becomes

* In his Surgical Pathology.

pyæmic, it is not because the phlebitis caused an absorption of pus, but because the patient had not the ability to react against the injury and the occurrence of those symptoms that characterize the condition known as pyæmia. His resisting and reactionary powers were defective. Veins, large and small, are cut in all operations, and must heal by inflammation, whether they are tied or not. If the pus gets in a vein, and thence into the circulation, it will do so because the patient has not the resisting power to avert the pyogenic process. In other words, he is predisposed constitutionally.

This leads me to formulate another rule, which is that *most, if not all, of the so-called infectious disorders are due almost exclusively, if not exclusively, to intrinsic and not extrinsic causes.*

These intrinsic causes may be formulated under the general head of predisposition, and this may conveniently be divided into hereditary and acquired.

The hereditary form may appear at, or shortly after, birth as an anatomical defect, or may only show itself during infantile development. On the other hand it may not exhibit itself till after the beginning of puberty. Warning may also be had of the existence of a defective tendency by some special subnormal physiological processes that are quite constant in, but peculiar to, the person affected.

The acquired predisposition may grow out of bad environments, as poor food, air, or light, exposure to cold or damp, or irregular mode of living; it may be due to intrinsic causes, as syphilis and other diseases, both local and general, or to bad practices or vicious habits. The degenerative period of life also furnishes abundant changes that go to make up a strong predisposition to diseases that had previously been ineffectual in encroaching upon the vitality of the organism. Every serious disease, like each grave operation, in fact all serious disturbances, are potent in lessening the vitality or resisting power of the individual, or, in other words, they aid strongly in the acquirement of a predisposition to disease.*

(*To be continued*).

*In view of the misunderstanding developed during the discussion of this paper, it seems not amiss to explain that by predisposition to surgical complications I do not mean predisposition to tuberculosis, or scrofulosis, inherited syphilis, or any of the well-known dyscrasiæ or cachexiæ, whether inherited or acquired; but a tendency irrespective of these to complicate traumatisms. Why do some women while in child-bed, after a typical labor, and days afterwards, without having had a bad symptom or any fever, develop a plugging of the femoral vein? Why do some women, without any apparent local or general trouble, develop the same condition? Allowing even the fallacious supposition to be true that the plug was derived from the uterine sinuses, where it was originally located as a clot, and we fail to explain why the clot, little enough to pass through the smaller uterine veins and those of the pampiniform plexus, should be arrested in a vessel of such large dimensions as the femoral vein, instead of going further down the limb, or, if hindered by valves and the blood current, into the heart and lungs. There is probably a double cause, local (in the vein) and general.

*Chas. D. Meigs, M. D., "Woman: Her Diseases and Remedies."

Medical Societies.

BALTIMORE GYNÆCOLOGICAL AND OBSTETRICAL SOCIETY.

(*Concluded from page* 143.)

Dr. H. thought it very probable that had Dr. Ashby been present when delivery occurred in his case, and rendered proper assistance with the forceps, as he certainly would have done, and promptly removed the placenta, his patient's life would have been saved. It is to the last degree important in all cases of labor occurring in women suffering from organic affections of the heart, that the accoucheur be present from the commencement to the close in order to render prompt assistance in any exigency that may occur. But it is not always easy to discriminate between organic and inorganic murmurs so as to determine whether a given case has a functional disorder or an organic lesion of the heart—a practical point of great moment, to which Dr. Ashby did not allude in his well-written paper. Some years back, Dr. H. had seen a gentleman in consultation with his good friend, Dr. J. W. Houck, of this city. Six physicians, some of them excellent auscultators, saw the patient; three thought the loud systolic murmur indicated grave organic disease, and three were equally confident that it was inorganic, and induced by extreme anæmia. The latter's opinion proved to be correct, as the murmur completely subsided under appropriate treatment.

In that remarkable book which so charmed the medical mind about a third of a century ago, its eminent author* directed special attention to the difficulties encountered in *ancæmia gravidarum* in distinguishing between true organic lesions of the heart, and what he terms "*seeming diseases of the heart.*" He draws, in his own striking and inimitable manner, vivid pictures of the latter, characterized by palpitation, great increase in the area of cardiac pulsation, dyspnœa, orthopnœa, etc. Even now, the chapter he devotes to the subject will well repay perusal. Dr. H. attended a bright mulatto

woman in the spring of 1862, during the last two months of her pregnancy, but was unable to be present at her accouchement. She was extremely anæmic, anasarcous, and suffered dreadfully from slight exertion. Anæmic soft and blowing murmurs were well marked over the heart and in the carotids, accompanied by a venous hum. But Dr. Meigs' statement that the most extravagant deviations in the heart's action in such cases are greatly lessened or wholly disappear so long as the woman remains at rest in the recumbent position, was beautifully exemplified. This is a diagnostic point of great importance; for, as Dr. Meigs forcibly states, though the derangements of the heart's action are frightfully aggravated, when organic lesions exist, by exertion, they do not wholly disappear in a state of profound rest.

Dr. George W. Miltenberger said that in his experience cases of confinement complicated by heart disease almost always resulted favorably.

Dr. Thos. Opie considered that, although the bellows murmur heard during pregnancy is generally due to hydræmia, yet he saw no reason why pressure of the enlarged uterus against the abdominal aorta should not cause a regurgitant murmur under certain circumstances at the aortic valves. He felt certain he had seen reference to the same idea in print recently. So long as there was the physiological slowing of the pulse following labor he felt safe, always considering an increase in the heart-beat shortly after labor as a warning of approaching hemorrhage, or later on of blood-poisoning.

Dr. Howard thought it very improbable that the pressure of the uterus or any intra-abdominal tumor against the aorta would cause *any* heart murmur. He would ascribe such a murmur either to anæmia or previous valvular disease.

Dr. T. A. Ashby closed the discussion by saying that he fully coincided with Dr. Erich's views in regard to the inadvisability of inducing premature labor or abortion in cases of pregnancy with advanced cardiac disease. There are two objections to the method: first, the effort of delivery in premature labor is, if anything, more injurious to these cases, and more liable to bring about disturbances of the circulation, than labor at full term. In the second place, premature labor almost of necessity involves the destruction of the child, and thereby jeopardizes two lives, whereas in labor at full term the life of the child is not necessarily complicated by reason of the existence of cardiac disease in the mother. In the case reported by Dr. Ashby, a vigorous healthy child was born, which to some extent compensated society for the loss of its parent. Dr. Ashby recognized the importance of the points stated by Dr. Howard. In the case he had reported the diagnosis of organic cardiac disease was carefully made and functional heart murmurs were discounted. The patient had no œdema, no anasarca, and her anæmia was not sufficient in itself to have accounted for the mitral regurgitation and aortic obstructive murmur. The patient had a previous history of rheumatic endocarditis, which unmistakably accounted for organic changes. He was clearly of the opinion that the hemorrhage following the delivery of the child was insufficient to account for the disturbance of the heart's action, and he believed that this loss of blood could have been avoided had he been present at the birth of the child. On the other hand, the hemorrhage was not sufficient in itself to have destroyed the life of the patient. Had the equilibrium of the circulation been provided for by compensatory arrangements, and the duty of maintaining the circulation been performed by the heart, its action would not have ceased. In referring to the prognosis of pregnancy in cardiac disease, Dr. Ashby agreed with the views expressed by the President and Dr. Howard. He thought Dr. Macdonald had taken too unfavorable a view of the prognosis. Macdonald had reported a mortality of 60 per cent., which was certainly very high. In a recent discussion before the Obstetrical Society of London (*Brit. Med. Jour.*, April 24, 1886, page 781), the subject had been discussed, and this view of Macdonald's prognosis had been expressed by several speakers. The practical point to be considered in connection with cases of pregnancy associated with organic cardiac disease, has reference to the treatment of the patient during labor. Knowing that cardiac disease exercises an unfavorable influence upon the prognosis of labor, the obstetrician should give close attention to these patients, and should see that the condition of the heart was not influenced by excitement or other causes liable to induce shock or suspended action.

Dr, W. E. Moseley reported the following:

A Case of Intra-peritoneal and Post-peritoneal Abscess.

Mrs. F., aged 25, a light mulatto woman, between two and three years ago, first noticed a painful swelling occupying the right iliac fossa, and which confined her to her bed for several days. The tumor developed rapidly, was accompanied by pain, was sen-

sitive to touch, and was coincident with a decidedly constipated condition of the bowels. The patient attributed the trouble to straining or bruising from carrying heavy market baskets. A blister was applied, and in a few days the swelling disappeared, and no more attention was paid to it until last November. At that time she was in the country nursing her sister, whom she had to lift and who was a very heavy woman, and while thus employed the swelling re-appeared. On her return home she was seen by various physicians, who gave her internal medication, but without producing any diminution in the size of the tumor.

I first saw her February 26, and at that time obtained the following history in addition to the facts already related; Menstruation had been regular and without marked pain until about seven years ago, when it ceased and has not re-appeared, but at each period since there has been some pelvic discomfort. She has never known herself to be pregnant. General health was always good until the first appearance of the tumor, nearly three years ago, since which time she has been failing. Bowels rather constipated, but appetite very good. Examination of the abdomen showed a well-defined oval tumor occupying the right iliac fossa, about six inches in its longest diameter, parallel to the crest of the ilium, and extending about three and a half inches toward the median line. It was somewhat sensitive on deep pressure, and had an elastic feel, as though there might be fluid confined beneath thick but tense walls. The swelling could not be felt per vaginam. There was a sharp cervico-corporeal anteflexion of the uterus, and on the left lateral wall of that organ was a small fibroid tumor about the size of a hickory-nut, with its attachment nearly on a line with the internal os. There was no connection between the abdominal tumor and the uterus. The bowels were constipated, but kept open by enemata and laxatives. The pulse averaged about 84, and temperature 99° +. The patient was confined to her bed nearly all the time from weakness, abdominal discomfort, and inability to walk. For about two months I tried the effects of counter-irritation with iodine and blisters, and the persistent use of heat, together with copious hot vaginal douches, and general tonic treatment; but the tumor increased slightly in size, and on April 20, assisted by Dr. C. H. Riley, a thorough examination was made under ether, which confirmed the results of the previous examinations. An aseptic hypodermic needle was introduced about two inches anterior to and on a line with the anterior-superior spinous process of the right ilium, and clear laudable pus withdrawn. Both Dr. Riley and myself thought that a free opening with drainage would give the patient the best chances of recovery in the shortest possible time; so, under the free use of $\frac{1}{2000}$ solution of bichloride of mercury, an incision two inches long was made two inches from and parallel to the crest of the ilium, and extending down to the peritoneum. The peritoneum and sac of the abscess were stitched together by two rows of interrupted sutures, three on each side, after the greater part of the pus had been removed by the aspirator. An incision was made between the rows of sutures, a rubber drainage-tube introduced and made fast to the abdominal wall, and the skin and muscle brought together by two silk sutures. About five ounces of pus were obtained. The abscess was washed out morning and night for several days with $\frac{1}{2000}$ bichloride solution, iodoform sprinkled around the incision, and the whole covered with tarred jute. The discharge was very slight from the first. On the second day the pulse reached 102, and temperature 101.9°, but after that the pulse ranged between 80 and 90, and the temperature between 98° and 99° F. in the axilla. The drainage-tube was removed on the fifth or sixth day, and the cavity washed out once daily. The patient sat up on the fourteenth day, and since then the cavity has been washed out every second day. The abdominal incision healed by first intention. There now remains a sinus extending about two inches inward and slightly upward, the induration is rapidly disappearing, and there is no more pus obtained than can be accounted for by the walls of the sinus.

The questions of special interest to me at the time of the operation were, in what tissue and from what cause did the collection of pus originate, and what was the prognosis? My opinion was that the abscess was intraperitoneal and due to an old perityphlitis, or in the cellular tissue behind the reflection of the peritoneum, with a decided bearing toward the former. The condition of the patient at the present time, I think, demonstrates pretty clearly that the abscess was not due to necrosed bone.

Dr. Howard had seen a somewhat similar case in a child four or five years of age. The abscess was opened freely and about a pint of pus evacuated. The child recovered.

Dr. Erich would consider the cause as probably perityphlitis.

Dr. Miltenberger thought such abscesses

frequently occurred without our being able to trace them to any specific cause. He thought the one reported by Dr. Moseley was probably situated in the cellular tissue behind the reflection of the peritoneum.

Dr. H. P. C. Wilson said he was absent at the last meeting of the Society when Dr. Chunn's paper, describing the removal of an ovarian tumor from a negro woman, was under consideration. As this operation was done at the Hospital for the Women of Maryland under his service, and by his assistant, he would be considered as endorsing the correctness of the case as reported should he hold his tongue. He now rose to protest against this case going on record as an ovarian tumor in a negro woman. It was clearly, to his mind, a tumor of the uterus. It grew from the whole posterior surface of the uterus as low down as the vaginal junction. It grew from the fundus uteri and also from the upper part of its anterior surface. It was attached to the left broad ligament and the left ovary. The tumor, the uterus, the left broad ligament, and left ovary, were so inseparably blended in one mass that he thought Dr. Chunn wisely decided that the only hope for the woman was to remove the uterus with tumor and left broad ligament and ovary as low down as they could be clamped. This he did, with the recovery of his patient. At the close of the operation, Dr. Chunn requested him to adjust his chain hysterectomy clamp prior to cutting away the mass; and in performing this act he had ample opportunity to observe accurately the growth of the tumor from the uterus and its adjoining attachments, and he was *then* satisfied that the tumor was uterine in its origin and growth, and he is equally satisfied *now* that it was a cysto-sarcoma of the uterus, and not an ovarian tumor. Although he had examined a great many negro women, he had never seen an ovarian tumor in one. He had consulted a great many physicians on this point, and had never found one who had seen an ovarian tumor in a negress. He had never heard or read of this kind of tumor being found in the African race. Dr. Atlee mentioned such a tumor as occurring in a woman three-fourths white; she was certainly not a negress. Dr. Chunn's operation was performed on December 22, 1885, and the patient died on April 24, 1886, after she had entirely recovered from the operation, and had been walking about the city for several weeks. Dr. W. T. Councilman, pathologist to the hospital, in his report of the post-mortem, says that he "found nodules on the surfaces of the liver and spleen, and all over the peritoneal surfaces. The omentum was rolled up into a solid cord as large as a child's arm. It extended into the pelvis and formed part of the mass found there. Microscopical examination proved the nodules to be sarcomas. It seemed certain that none of the tumors could be regarded as primary. It is probable that the original tumor, which was removed by Dr. Chunn, was a sarcoma, or had some sarcomatous tissue in it."

Dr. Howard said that he differed entirely from Dr. H. P. C. Wilson in regard to the diagnosis of the case under discussion, and was as positively certain as he could be in respect of any diagnosis whatever, that the case was one of *ovarian* cystoma. At the Woman's Hospital there is a law requiring that no capital operation can be undertaken in the Hospital without consultation between the surgeons in charge. In obedience to this law, Dr. Chunn brought the woman to Dr. Howard's clinic. There were present Dr. H.'s assistants at the hospital, Dr. Chas. H. Riley, Dr. Chas. O'Donovan, Jr., and also Dr. Chunn and Dr. L. Ernest Neale. Each of these gentlemen carefully examined the case, and all agreed that it was one of *fibro-cyst of the uterus*. Dr. H. dissented, and expressed the opinion that it was an *ovarian cystoma*. Dr. Neale requested Dr. H. to give the reasons for his opinion, and Dr. H. did so. It is well known that the frequency or infrequency of a disease is a matter of great importance in questions of difficult diagnosis, and that when one disease is frequent and the other proportionately rare, the physician naturally inclines to a diagnosis of the most common affection. But that, as in the negro race, ovarian cystomata and uterine fibro-cysts are almost equally among the rarest of all race affections in frequency of occurrence as an element of differential diagnosis, is not available. Still, it is a well-established fact that *ovarian* cystomata are everywhere much more frequent than uterine fibro-cysts; hence, in any case in which the diagnosis is narrowed down to these two affections, the chances are in favor of *ovarian* disease, unless they are impaired by some other clinical data that may be fairly considered as an offset. But Dr. H. knew of no such consideration that could be advanced in this case; on the contrary, they rather increase the evidence in favor of the case in hand being *ovarian*. Thus, we all know that the *rate of growth* in the two affections is, in an immense majority of cases, very different, and that uterine fibro-cysts usually grow much more slowly than ovarian cysts. In

Dr. Chunn's case about three years had elapsed since the woman had noticed that her abdomen was gradually enlarging symmetrically, from below upwards, and then measured fifty inches in circumference around the largest part of the abomen. And certainly it is *not uncommon* to observe ovarian cystomata developed to such a size in three years, while on the other hand it is *very uncommon* for a uterine fibro-cyst to attain such a size in the same space of time. Again, the age of the patient militated strongly against its being a uterine fibro-cyst. Thus, of 28 cases of fibro-cysts of the uterus cited from various authors in Dr. H.'s address before the American Gynæcological Society in Washington city in September last, only four were under 34 years; generally they were from 40 to 50. The only case of fibro-cyst of the uterus that Dr. H. had seen published as occurring in a woman as early as 24 years of age, was one reported by Dr. Hunter McGuire in the second volume of the *Philadelphia Medical Times.* But Dr. Chunn's case was only twenty years of age. Has Dr. Wilson ever seen or heard or read of any case of uterine fibro-cystic occurring at that early age in any woman of any country, race, or condition in life? But who is it that does not know that ovarian cystomata are *common at that age, and long before?* And Dr. H. repeated that, in respect of frequency of occurrence, whether in this country or abroad, it is a universally-admitted fact, that a fibro-cystoma of the uterus in comparison with an ovarian cystoma is a *very rare disease at any age.* In his immense experience, embracing more than 1000 laparotomies, Lawson Tait has only once seen a fibro-cystic tumor of the uterus.

Now, let us consider what light the operation threw upon the question at issue. When Dr. Chunn had cut down upon the cyst, what color did it present? It is well known that a dark and congested appearance is characteristic of a fibro-cyst of the uterus, and that it strongly contrasts with the clear, pearl-like conjunctival blue of most ovarian cysts. And so typical was the appearance of an *ovarian* cyst in Dr. Chunn's case, that when Dr. Wilson saw it, he said: "Howard, I believe your diagnosis is right." When the fluid was drawn off, it presented the dark chocolate appearance and unctuous character so often seen in ovarian cystomata. But when Dr. Chunn drew out the cyst, Dr. Wilson reasserted his original opinion that it was a fibro-cyst of the uterus. Dr. Chunn hesitated what to do, but finally removed the uterus somewhat above the junction of the cervix with the corpus. Dr. J. Edwin Michael, *Professor of Anatomy* in the University of Maryland, then carefully examined the specimen, and demonstrated to the entire satisfaction of all the physicians present who had diagnosed the case as a uterine fibro-cyst, that they were completely mistaken, with the single exception of Dr. Wilson, and that it was an *ovarian cyst.* When the specimen was subsequently exhibited before the Clinical Society of Maryland, Professor Michael said: "An examination of the specimen will show that the uterus is free from adhesions to the tumor on both its anterior and posterior surfaces, and is only connected with it by means of adhesions of the broad ligament. The tumor, in other words, having its proper pedicle on one side, had become adherent to the broad ligament on the other side, and these adhesions could have been ligated and cut, and the tumor removed, as is usual in such cases, with less danger to the life of the patient than that to which she was exposed in the operation done."* And, as Dr. H. was informed, there was not a dissenting voice in regard to the diagnosis of *ovarian* cystoma among all the physicians present, who saw and examined the specimen. Thus it appears that all the physicians who saw the woman before the operation was done, and committed themselves to the diagnosis of a fibro-cystic tumor of the uterus, and were subsequently present at the operation and personally examined the specimen, frankly confessed that they were mistaken in their diagnosis, and that Dr. Howard's diagnosis, from first to last, was correct—with the sole exception of Dr. Wilson, who stands solitary and alone in his erroneous diagnosis. And, further, that all the physicians at a meeting of a large medical society, who had never committed themselves to any diagnosis, and only saw and examined the specimen, were as one in the diagnosis of *ovarian* cystoma.

Dr. Chunn said that having reported the case under discussion as an ovarian tumor, which diagnosis had been questioned, he would give his reasons for the opinion he then held and still continues to hold. The whole history of the case pointed to ovarian disease, viz., the short time of growth (3 years), the youth of the patient (20 years), the shape of the abdomen, and the area of dullness and fluctuation. The facies ovariana was strongly marked. Moreover, when the abdomen was opened, there appeared a cyst of a *glistening, pearl-like hue,* containing a pathognomonic thick, *chocolate-colored* fluid,

*Maryland Medical Journal, April 24, 1886, p. 503.

which did not coagulate. These signs were given in every book on the subject he had over read as certain and undoubted evidence of ovarian cyst. In regard to taking out the uterus, he wished to make himself equally plain. The uterus was imbedded in the anterior wall of the sac, as he had before said, and was attached by the posterior and left lateral aspect, the right border only being free. All those who saw the pelvic relations *in situ*, viz., Drs. O'Donovan, H. P. C. Wilson, and himself, agreed that the attachments were of the most intimate character. The opinion of the other gentlemen present was derived from the relations of the tumor to the uterus *after extirpation*, as they had no opportunity to inspect the relations while in the pelvis. Their opinion was incorrect, and for the following reason. When the uterus and sac were cut away, in order to leave plenty of tissue in the bite of the clamp, the amputation was begun high up above the chain, and was made in an obliquely downward direction, so that, when the sac was at last taken away, only the left horn of the uterus went with it, the rest of the uterine tissue being trimmed away afterwards. This occurred because the chain of the clamp was hidden from view by the overlapping parts. And again, the uterus and sac being lifted up by an assistant as the cuts were made by scaipel or scissors at *different* distances above the clamp, the parts all spread out in such a manner that the relation of the uterus to the sac was simply impossible to be made out *after removal*. At the time of operation, he was of the opinion that those present were in favor of hysterectomy. Certain it is that no dissenting voice was heard until after the operation was completed.

Dr. Moseley was present at the meeting of the Clinical Society at which Dr. Chunn reported his case and exhibited the specimen. He had carefully examined the specimen, and had no doubt but that it was an ovarian cyst, and felt certain that was the opinion of all who examined the specimen, among them being Drs. Keirle, Councilman, and Tiffany. He did, however, consider that, *judging from the specimen shown*, the operation, *as done*, was not justifiable, as he believed the cyst could have been ligated and removed without involving any portion of the uterus.

Dr. Chas. O'Donovan, Jr., said he too wished to add a few words in regard to this case. Dr. Chunn requested him before the the operation to stand opposite him and sponge, which he did during the entire operation, so that, after him, he had the best opportunity of any one to see the condition of the parts in the abdominal cavity before the removal of the tumor; and he could state without hesitation that before the tumor, with the uterus, had been cut away, it was next to impossible to make out the exact amount or the locality of the attachments that existed. He knew that Dr. Chunn had been very severely criticised in his method of operating, by those especially who saw the tumor for the first time after it had been removed from its surroundings, when the cut edges of the enormously thickened broad ligament could be turned back, thus exposing the tumor from below, and giving a clear view at once of the location of the pedicle and its extent; but he desired to say in defense of Dr. Chunn, that the view he had of it during the operation and from above was very apt to mislead. The tumor, in developing, had gradually spread out the broad ligament and pushed it before it, being all the while intimately connected with its inner surface, so that to say at the time of the operation, when through the escape of the contents of the cyst mixed with blood the appearance of the different tissues in the cavity had become very indistinct, where the exact ending of the broad ligament lay on the cyst wall, was next to impossible. In more than one operation that he had witnessed, he had seen the same thing happen, but usually, by very careful inspection, it was possible to make out the line of junction, when by cautiously peeling off the ligament the cyst could be shelled out as it were from its covering. From the criticisms made upon this case, one might infer that Dr. Chunn hastily applied the clamp and cut off the uterus without making any examination of the attachments whatever, but nothing could be further from the case; he very carefully went over the mass more than once, both in front and behind, but nowhere could he make out the line of junction. It was only then that he determined to do a hysterectomy in preference to cutting away the great mass of the tumor and leaving part of the cyst behind. After the operation, when Professor Michael had demonstrated that the tumor was not attached directly to the uterus, as was apparent from the view beneath the broad ligament, it seemed plain to all, except Dr. H. P. C. Wilson, that the uterus should never have been removed; but he would repeat that until that moment it was impossible for any one to say for certain what was the attachment of the tumor. One word for the diagnosis. Before the operation, as Dr. Howard had stated, he and all

who saw the case, except Dr. Howard, inclined to the diagnosis of fibro-cyst of the uterus, but with a considerable margin of doubt; after the operation, we all, except Dr. H. P. C. Wilson, conceded that we had been wrong, and that the tumor was ovarian.

Dr. A. F. Erich exhibited a new tourniquet he had invented for the temporary compression of the stump in supra-vaginal amputation of the uterus. The tourniquet has the usual male and female screw, but the canula is made somewhat heavy, and the eye at the end large enough to allow the loop of a rubber tube the size of the little finger to be passed through. The ends of this rubber tubing, which is used in place of wire or catgut, are tied together and hooked over a stout hook attached to the shaft of the instrument. By this arrangement the tubing can be repeatedly loosened and tightened without the annoyance and delay occasioned by trying and untying the knot, or danger of bruising the parts.

The general impression of the members present was that the instrument would prove a very useful adjunct in the cases for which it was intended.

Dr. Robt. T. Wilson exhibited a new forceps for compressing shot, to be used in any plastic operation in which shotting the sutures was desired.

The general opinion expressed was that the forceps were unnecessarily heavy and the jaws too wide, as they would be apt to hide the suture they were fastening.

Periscope.

Case of Osteo-sarcoma of the Inferior Maxilla; Excision of the Growth—Weight Five and Three-quarters Pounds; Subsequent Œdema of the Glottis and Laryngotomy; Death on Sixth Day of Pulmonary Thrombosis.

Dr. A. B. Miles thus writes in the *New Orleans Med. and Surg. Journal* for July:

On March 31, 1886, a lean-looking but well-grown colored boy, aged seventeen years, entered the Charity Hospital, presenting an osteo-sarcoma of the inferior maxilla. His general health seemed to be in no wise impaired by the presence of the tumor; and, up to the time of his coming to the hospital, he had done the work of a farm laborer.

The tumor appeared in March, 1883, as a hard, painless lump at the symphysis; and, in three years, attained the remarkable size shown in the accompanying plates. For two years and nine months, it grew gradually; then, for three months prior to admission, it increased in size and rapidly. Upon entering the hospital, the following measurements were recorded: Occipito-frontal circumference of the boy's head, 22 inches; circumference of the tumor, 19 inches; measurements from the lobe of one ear to the opposite, 21 inches. The growth involved the maxilla from a point midway between the symphysis and the right ramus, to the articulation on the left side. Its encroachments upon surrounding structures may be inferred from the measurements given and the extent of the jaw involved. It bore down in front upon the thyroid cartilage, impeding its movements in deglutition, and, externally, pressed quite out of their natural course the jugular and carotid vessels. The enlarged ramus filled up the space between the mastoid process and the posterior border of the superior maxilla; and a lobulated projection from its inner surface pressed upon the pharynx. The malar bone and superior maxilla were both deformed by pressure. The former had been lifted out of its natural relations, while the pressure against the superior maxilla had been so great as to displace inward the alveolar process and molar teeth, and crumple the hard palate. The mass so nearly filled the mouth as to interfere with mastication and deglutition. Figs. 1 and 2 represent the appearance of the tumor from two points of view.

The tumor was entirely painless. It was simply an inconvenience, because of its size and weight, and its interference with surrounding structures. It had contracted no adhesions by infiltration or inflammation. Within the limits restricted by the size of the growth, the jaw was freely movable. Some of the adjacent lymphatic glands were enlarged, but the enlargement was simple and due to irritation from pressure. It is not in the nature of these osteo-sarcomatous growths to infiltrate. There were no evidences of constitutional infection.

In view of the boy's general good health, the freedom of the tumor rrom attachments to hinder its removal, and the strong proba-

bility of a permanently successful result, should the patient withstand the immediate dangers of the operation, it was determined to excise that part of the maxilla involved in the neoplastic growth.

Fig. 1.

The operation was performed Tuesday afternoon, April 6, in the presence of Drs. Bickham, Jamison, Archinard, others, and the resident staff of the Hospital; and with the assistance of Drs. Chaissagnac and Parham, to whom the writer feels specially indebted.

The following are the steps of the operation, described briefly: The patient was etherized, but in the latter part of the operation, when it was impracticable to prevent the risk of blood entering the windpipe, the anæsthesia was not complete. The tongue was threaded with a silver wire, and entrusted to an assistant. The first incision ran along the anterior aspect of the tumor, extending from the right angle of the jaw to a point opposite the lobe of the left ear. The second incision was carried along the under surface of the tumor, connecting with the first so as to leave an eclipse of redundant skin attached, and locate the line of union of the flaps about where the inferior border of the maxilla would be. The facial arteries were ligated before section, so the larger veins were clamped before division; and the quantity of blood lost was inconsiderable. The under-flap was dissected first, then the upper, leaving the cavity of the mouth widely open. The body of the jaw was sawed in front of the right ramus, and while an assistant lifted the tumor so as to make traction, the mucous membrane was peeled off and the posterior attachments severed. The most tedious step of the operation was the dissection of the left ramus, which had developed enormously, filling up the space between the mastoid and the posterior border of the upper jaw, and giving off a projection which rested against the pharynx at the base of the skull. The close relations with the internal maxillary artery made the dissection more tedious.

The patient bore the operation well, and suffered from shock less than expected. The wound was closed with deep sutures of silver wire

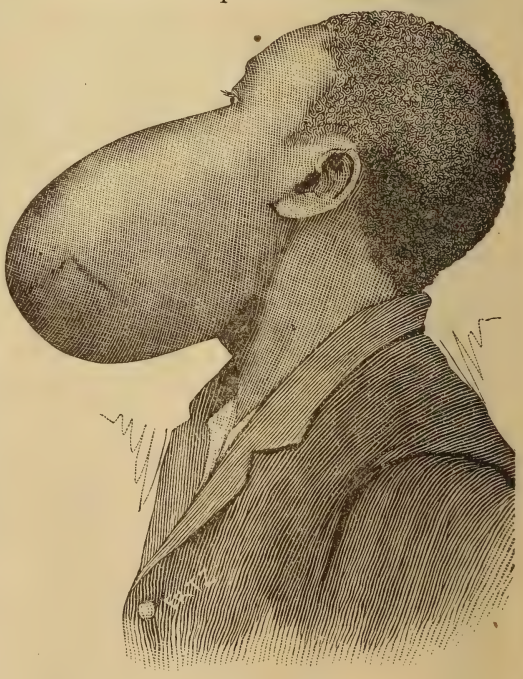

Fig. 2.

and intermediate sutures of silk-worm gut, dusted with dry iodoform, and dressed with the mercurialized materials—gauze, absorbent cotton, and gauze bandages.

It was impossible to appose accurately the surfaces of such a large and irregular wound. Consequently suppuration ensued, pus formed in the space between the mastoid process and the pharynx, and escaped at the upper end of the incision. An accumulation also gathered under the lower flap on the left side, and escaped along the course of the facial artery. The wound was irrigated daily with carbolized water, and dressed as above described.

On the morning following the operation the tongue was extremely œdematous, and the respiration labored and unsatisfactory. The patient was very restless and complaining. The symptoms very soon indicated an increasing œdema of the glottis. In the swollen condition of the tongue and fauces, intubation of the larynx was impracticable; laryngotomy was performed, and a tracheal tube inserted. The operation, as usual, afforded immediate relief, and added much to the patient's comfort subsequently, obviating the necessity of the painful traction on the tongue, of which he complained bitterly. The tracheal tube, no longer necessary, was removed at the end of forty-eight hours. No harmful effects whatsoever followed the laryngotomy.

On the following Monday morning the patient seemed to have successfully run the gauntlet of his greatest dangers and entered upon a fair way to recovery. He had at all times nourished satisfactorily. In spite of the high range of temperature during the first seventy-two hours, and the rapid pulse-beat, he expressed himself encouragingly; and really the chances never seemed to be adverse to his recovery.

However, during the forenoon of this day, patient became restless and slightly delirious. At noon his temperature had risen to 102⅘° F.; pulse to 140; respiration to 46. Observe the relative frequency of the respirations. As the afternoon advanced, his general condition became more critical, and he breathed with exceedingly great difficulty. He died of pulmonary thrombosis, having entered the sixth day after the operation. His death was unexpected, and the cause may be regarded as accidental.

The following account of the autopsy, made by Dr. P. E. Archinard, is given in the doctor's own words:

"The patient's general appearance was emaciated. The wound from the operation was united superficially in part of its extent. There were found two pockets of pus, one low down in the neck, and the other at the upper margin of the wound; the surface of the wound was suppurating, and at the bottom could be nakedly seen the carotid artery and internal jugular vein with one of its large tributaries.

"The abdominal organs and pleura were normal, the lungs anæmic. The heart was in diastole, with the left cavities empty. In the right ventricle, adhering to the columnæ carneæ and tricuspid valve, was a large firm ante-mortem clot, extending into the pulmonary artery to its smallest ramifications in both lungs. This thrombus, which, to all appearances was the immediate cause of death, did not occupy the whole calibre of the larger arteries; but in the lung substance seemed to completely fill up the vessel, though no embolism was found."

Figure 3 represents the macroscopical appearances of the tumor. Its external surface was even and symmetrical; its internal lobulated. A, indicates the head of the condyle; B, the lobular mass growing from the inner surface of the ramus, between the mastoid and the superior maxilla, toward the base of the skull; C, the only ulcerated surface, which was quite superficial and exposed at the orifice of the mouth. Observe the disarrangement of the teeth. In its structure, the tumor was typical of the osteo-sarcomatous growths, and weighed 5¾ pounds. It has been preserved in the Pathological Museum of the Hospital.

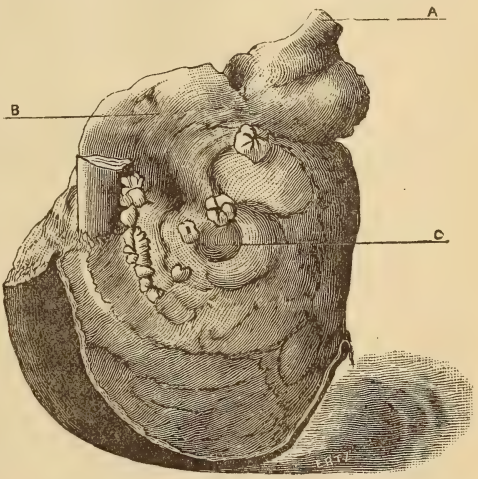

FIG. 3.

"MAN, ye might gie me a pennyworth o' something. I dinna ken the name o't, an' I forget what it's for; but ye'll ken yersel."

A New and Original Method of Surgical Dressing.

Dr. Charles W. Strobell, of Middletown Springs, Vt., writes to the *Medical Record* that he was led by the paper of Dr. Hamilton, and the criticisms upon it in recent numbers of the *Record*, to consider what improvements might be made upon the modes of antiseptic dressing now in use. The main objection to the ordinary dressing of cotton-wool, gauze, etc., is that it conceals the wound from view, so that inflammation, secondary hemorrhage, and other accidents, cannot be detected at their onset, and may become only too well established before the surgeon becomes aware of their existence. In order to obviate this, Dr. Strobell proposes to cover the wound with a thin glass globe, so constructed as to fit closely to the part, provided with two openings for drainage-tubes and a large opening on the top, to permit of access to the wound, in case of need, without removing the globe. These openings are provided with glass stoppers, so that they can be hermetically closed. The base of the globe is provided with a flange, and its sides, up to within two inches of the drainage-tube openings, are roughened so as to facilitate the adhesion of the isinglass plaster used in sealing it. When applied to stumps after amputation, a thin rubber band, three inches wide, is applied over the flange, so that it rests with one-half its width on the integument of the limb to secure additional safety. The flange is covered on its external surface with isinglass plaster, adhesive on both sides, so that the band of rubber shall adhere firmly to the globe. In the case of an amputation at the knee-joint, after the sutures and drainage-tubes are in place, the wound is capped with a disinfected globe of the proper size to fit snugly over the limb, the drainage-tubes in the globe being on a line with the anterior surface of the wound. The rubber band is now turned down over the limb, and strips of adhesive silk, one inch in width and twelve inches in length, are applied longitudinally from the upper part of the ground portion of the globe up the limb, each strip overlapping slightly the preceding one, a final strip being placed circumferentially around the flange and covering in the ends of the longitudinal ones. In a case of laparotomy an oval-shaped globe may be applied in a similar manner.

The following are the conclusions of the writer: "The method commends itself to the profession:

"1. In the complete isolation of wounds that can be obtained in the event of infection of hospital wards by erysipelas, etc., as the globe can be hermetically sealed.

"2. All changes can be noted clearly at any moment, with the minimum amount of discomfort to the patient, thereby increasing largely his chances of recovery.

"3. The perfection of drainage, which has never been obtained in so great a degree, obviating the necessity of soaking off bandages saturated with dry pus, blood, and serum, often adhering so firmly to the wound that the most gentle manipulation is required to avoid laceration of the tender granulations.

"4. Secondary hemorrhage can be detected at the earliest possible moment.

"5. The first evidence of inflammation can be noted and its movement forestalled by removal of the cause.

"6. The action of topical remedies can be observed without exposure of the wound to the air.

"7. The dressing can be adapted to wounds of almost every description.

"8. Refrigerant and thermal water-dressings can be applied with the utmost facility.

"9. Lotions or powders can be easily applied to the wound through the main opening in the globe without disturbing the dressings.

"10. If it is desired to prevent the ingress of infected air, the drainage-tubes can be filled with plugs of iodoformed or carbolized cotton.

"11. In the event of inflammatory swelling, rendering the constriction of the base of the globe excessive, the apparatus can be replaced by one of larger size with less expenditure of labor and time than is required in the application of a Lister dressing.

"12. Facility is afforded for determining the therapeutical effect and germicidal action of direct sunlight in the treatment of wounds.

"13. By means of long, slender forceps and scissors, the sutures, drainage-tubes, and adhesive plaster may be easily removed through the main aperture in the globe.

"14. The weight of the apparatus is not as great as that of the ordinary Lister dressing.

"15. If perfectly applied, there should be no more constriction of the limb than results from moderately firm bandaging.

"16. The expense is comparatively light, as the globes can be used indefinitely, being thoroughly disinfected by boiling water.

"17. The apparatus may be adapted to any external surface by taking, in special cases, wax impressions, and transmitting them to the manufacturer.

"In conclusion, I will say that my claim to originality is, in my opinion, well founded, as nowhere in surgical works have I seen glass mentioned, used in the way I have indicated, as a protective dressing."

The Preventive Treatment of Syphilis.

Dr. Charles E. Jennings thus writes in the *Lancet*, July 17th:

The following case is of interest, as showing how syphilis may be prevented by prompt local and general treatment before the chancre has arrived at maturity.

Early in November, 1885, Mr. A. B. C. consulted me for an eczematous affection of the skin, which itched intensely, associated with a few papules and vesicles, the eruption being sparsely scattered over the loins, buttocks, back, and upper arms. An aperient was prescribed, and glycerole of lead applications were ordered, but on November 11th the disease remained *in statu quo*. The aspect of the dermatitis, in part, suggested scabies, but the integument was healthy at those points which are specially prone to become the seat of scabies, viz: the clefts between the fingers and the flexures of the wrists. Moreover, the sarcoptes hominis was not detected microscopically, after careful search in the ordinary manner. The case was further complicated by the recent appearance of a hard, elevated nodule, the size of half a pea, with an inflammatory zone around, situated on the dorsum of the penis immediately behind the corona in the median line. There was a history of impure contact, and nearly three weeks previously the covering of the penis had become abraded during coitus at the precise spot where this small nodule had developed during the past three or four days. The lymphatic glands in both inguinal regions were slightly enlarged. The physical condition of the lesion on the penis led me to consider it a hard chancre not yet arrived at maturity, and, being immature, the prompt destruction of the chancre might arrest the elaboration of the syphilitic virus at the point of inoculation, and its absorption therefrom. Accordingly, the chancre and surrounding parts were freely painted with a solution of hydrochlorate of cocaine, to ensure anæsthesia, and the chancre was destroyed with Paquelin's cautery. I suggested that Sir William Jenner's opinion should be sought with reference to the skin affection. On November 12th, Sir William considered the dermatitis due to scabies, and that its origin around the loins and buttocks was caused by contagion implanted during congress coincident with the receipt of the syphilitic virus. He suggested the application of sulphur ointment to the affected skin, and thought that the free exhibition of mercury internally was also advisable in order to combat the effects of any portion of syphilitic virus already absorbed. This treatment was fully carried out, and the dermatitis quickly disappeared. The sore on the penis healed under iodoform dressings. The internal use of mercury was discontinued after six weeks, the patient soon regaining his usual health, and none of the secondary manifestations of syphilis have appeared. The success which followed the destruction of the chancre in this case by Paquelin's cautery, with the simultaneous employment of mercury, leads me to strongly recommend this course for syphilis, *before the chancre has arrived at maturity*, in preference to the opposite plan adopted by so many, viz: that of waiting for the appearance of secondary manifestations before commencing anti-syphilitic treatment. The use of cocaine is invaluable as rendering the caustic application painless.

Simultaneous Ligature of Right Carotid and Subclavian Arteries for Aneurism of Ascending Portion of Arch of Aorta.

J. A. Kelly thus writes in the *Lancet*, July 10:

The following case came under the care of Surgeon-Major E. Lawrie, M. B., M. R. C. S., Residency Surgeon, Hyderabad, Deccan, with whose permission I send it for publication.

W. de P——, a Eurasian, aged thirty-eight, had been under treatment since the early part of 1884 for repeated attacks of angina pectoris. He was also troubled by a hoarse cough, accompanied by frothy expectoration. The only treatment that afforded him any relief was hypodermic injections of morphia. In March, 1885, an aneurism was detected by Brigade-Surgeon T. Beaumont in the ascending portion of the aortic arch; and in August pulsation appeared on the right side of the upper part of the sternum. After a time three ribs were eroded, and a pulsating tumor as large as a tennis-ball showed itself under the skin. There was difficulty in swallowing solid food, which was rejected as soon as it passed the pharynx; and the patient was obliged to live on liquids, which he had to swallow carefully and slowly for fear of being choked. The right side of the neck and face was œdematous and livid; the voice was changed to a whisper; there

were paroxysms of angina with urgent dyspnœa, and a very troublesome cough. The pain had greatly increased, and, by preventing sleep, was impairing the patient's general health. No benefit was derived from absolute rest, Tufnell's diet, and large doses of iodide of potassium, and it was therefore decided to tie the common carotid and subclavian arteries.

On October 22, a hypodermic injection of morphia having been previously administered, the common carotid and subclavian arteries of the right side were ligatured, under the spray, with carbolized catgut. Chloroform was administered for the first incisions. Afterwards, anæsthesia was kept up principally by the local application of a 10 per cent. solution of cocaine. The edges of the wounds were brought together by horsehair sutures, and thickly dusted with iodoform, and dressings of cloth prepared in a 1 per cent. solution of perchloride of mercury in blood-serum, and dried, were applied. He was ordered fifteen minims of antimonial wine in an ounce of water every two hours. In the evening the pulse and temperature (which before the operation were 90 and 98° respectively) rose to 120 and 101.4°, but subsided the next day, and the wounds healed without inflammation by the first intention. Most of the urgent symptoms connected with the tumor abated within the first week after the operation, and the patient's general condition gradually improved, so that he was able to leave the hospital on December 18. The radial pulse returned to the right wrist eleven days after the operation.

The aneurism now (February, 1886) appears stationary, but still pulsates ; pain has greatly decreased ; swallowing is easily performed; and, with the exception of a dry cough, there are no pressure symptoms.

An Unusual Case of Malarial Fever.

Dr. W. G. Henry thus writes in the *American Lancet* for July:

Common as are the number of case of intermittent fever in this section of the country, I think the one I wish to report will prove at least slightly interesting in point of two reasons: Firstly, as being quotidian, and secondly as two exacerbations occurred within the twenty-four hours, making it "double quotidian."

Mrs. M., æt. 25, four months pregnant with first child. Complained of severe chills, followed by feverishness and sweating every day about 2 p. m., the attack lasting altogether about two hours.

Again, at 8 p. m., she experienced a similar onset of chills, fever, and sweating, just as had occurred six hours previously. Towards midnight she grew cool and would fall into a comfortable sleep and awaken in the morning feeling fairly well, when the thermometer would register about 99° F. in the mouth.

The rigors were so distinctly marked and occurred with such regularity that the diagnosis was very easy and the case most interesting from its being so well marked and rare a form of intermittent fever.

Proceeding as is usual in such cases, I administered quinine bisulphate; I gave it in capsules, each capsule containing five grains of the drug, and repeated the dose every three hours, doubling it about two hours before an expected rigor.

After three days of such treatment, I found the evening excerbation had disappeared, but the afternoon one remained; however, not so well marked.

In five days all rigors had ceased, and the patient felt quite well and able to perform her household duties.

I ordered her to take quinine thrice daily for a week, and my patient fully recovered to remain quite well until I was called to attend her in her confinement five months later, when I delivered her of a fine healthy female child. Here, again, malaria was her enemy and prevented her making the usual steady recovery, delaying it three or four days.

Different Preparations of Thallin in Enteric Fever.

Mr. Mayrhofer, during an epidemic of enteric fever occurring in a Bavarian regiment, employed thallin in three different forms—namely, the sulphate, the tannate, and the tartrate; and obtained highly satisfactory results from them all. He gave the drug according to Ehrlich's continuous system, the doses being generally 0.2 gramme, repeated when the temperature rose. From 1.0 to 2.0 grammes were given per diem. The total quantity required varied from 8 grammes in mild cases to 26 grammes in severe cases with relapses. After taking the medicine, a profuse perspiration occurred, which invariably appeared to improve the patient's condition. No unpleasant effects were ever observed. There were altogether eighty-eight cases, of which three (that is, 3.4 per cent.) died. It was not possible to say that one of the three preparations presented any marked differences in its action from the other two.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

CONNECTION OF SOME EYE DISEASES WITH NEIGHBORING LESIONS.

That affections of the mucous membranes of the nose frequently cause sympathetic diseases of the eyes is well known. The discharge of the lachrymal secretion through the nostrils forms alone a connection which may easily be the path of the progress of morbid conditions by continuity. But there are also some pathological states not so near to the eyes, and yet with sympathetic connection. We ourselves have seen occasionally inflamed submaxillary glands, especially before suppuration developed in them, and while the tissues go on swelling, give rise to conjunctivitis and even corneal inflammation of the eye, usually first on the same side, and especially if not neglected not rarely also attacking the opposite side. Some believe that these inflammations are due to circulatory disturbances. But if so, why is it just the eye that suffers from it? Why not rather some other still nearer tissue or organ? A better explanation is given us by the theory of bacteria, for the minute capillaries of the eye being smaller than any in their neighborhood may easily be obstructed by micro-organisms, which, starting and multiplying at the original seat of lesion, are finally carried into the circulation, and thus give rise to the eye inflammations mentioned.

Two articles have recently been contributed to the literature of the subject in question, viz., one by Dr. Ziem, of Danzig, in the *Allg. Med. Centrl. Zeit.* 20, 1886, and another by the same physician in No. 32 of the same journal. In the first article he refers to the frequency with which pharyngeal diseases produce inflammatory states of the eyes. Especially tonsillitis, whether acute or chronic, plays an important role in this respect; and some forms of chronic conjunctivitis, if due to this cause, cease only after the pathogenic element is removed by the extirpation of these glands.

In the second article Dr. Z. speaks of the catarrh of the Schneiderian mucous membrane, and cites cases to show how this condition produces sympathetic inflammation of the eyes. He ascribes the causal commotion to disturbances of circulation, though he admits that an aseptic treatment, if strictly carried out, has the most success. If we assume the theory of circulatory disturbances to be correct, we cannot explain the beneficial action of disinfectants or germicides.

One thing is sure, the sooner we get rid of the first morbid state of the kind mentioned the better it will be for the patient, and the

more those eye diseases will be prevented which are too often neglected by practitioners as unimportant, though many an eye has suffered irreparable damage from them.

PEDICULOSIS PALPEBRARUM.

Within the short time of two weeks three cases of pediculosis palpebrarum came under attendance at the eye clinic in Erlangen. As in each case the lice had been taken for blepharitis ciliaris by the physicians previously attending the patients, Dr. L. Rosemeyer came to the laudable conclusion to draw the attention of practicing physicians to their diagnosis (*Münch. Med. Wochenschrift*, 9, 1886).

The lice, which work themselves deeply into the skin and sit with their heads in the hair-follicles, look like yellowish-brown formations slightly larger than a pin's head, and may well deceive the observer, to whom they may appear as crusts adhering to the external margin of the lid. They can be, however, best recognized near the lashes, as in consequence of the ova there deposited, they appear to be completely covered with a brownish-black powder.

Occasionally the true picture of the pediculosis is masked by the symptoms of an eczema due to the scratching. In such case only a careful examination of the lashes by a magnifying glass can determine the true condition of things.

Besides inunctions with salve of white or yellow precipitate, the removal of the ova from the lashes is of the greatest importance, and it is best accomplished by laying the lashes on some firm support and by scraping off the ova with a dull knife. If such is not done the disease is apt to return a few weeks after a cure had apparently been established.

Notes and Comments.

Sixty Cases of Sciatica Treated by Galvanism.

In the *Lancet* (July 17), Dr. W. E. Steavenson publishes the details of these cases, and thus concludes:

"The above sixty cases have been more or less under my care. Thirty-seven have been cured; one had a return of sciatica and was cured a second time; eleven improved only; two did not improve; concerning nine, I am uncertain as to the result; and two are still attending the hospital. Of those that recovered, three cases were cured with one application, two required two applications only, seven cases were galvanized four times each, two were galvanized five times, one case required six times, four cases seven times, five cases eight times, one case nine times, four cases ten times, two cases eleven times, one case twelve times, one case fourteen times, and three patients came fifteen times before they were satisfied that they were cured; one patient escaped my observation, and managed to get one or other of the students to galvanize him twenty-five times before I stopped his coming; he had been free from sciatica for several weeks. Of the cases which were not successful, one patient was, after death, discovered to have extensive necrosis of the ischium, with a sequestrum of dead bone. Another, a lady, was at the time suffering from some malposition of the uterus, which was tilted over on to the side in which the pain was felt, and no doubt exercised some pressure on the roots of the nerve. Although in this case the sciatica was not cured, the patient was so much benefited that she was able to get about the house again after eight applications. Before electricity was tried she had been confined to her bed for five weeks. With regard to the second unsuccessful case, I cannot well assign a reason for its non-improvement. The patient was a gentleman who had spent many years in the East Indies, and had suffered from dysentery and ague. He attended and was galvanized eight times, and as he was not then free from pain he did not care to continue the treatment. He tried several remedies afterwards, with the same unsatisfactory result. Perhaps if he had persevered longer with the galvanism he might have been cured, for several of the hospital patients attended as many as ten or fifteen times before they were quite relieved; but there is more difficulty in obtaining the prolonged and regular attendance of a patient who has to pay for each application than of one who gets his treatment gratuitously. The cases included in my list bear out the favorable opinion expressed by Dr. Stone, in his recent Lumleian Lectures, of the action of electricity in the treatment of sciatica."

A Case of Cholecystotomy.

The rather recent revival of operative procedures for the relief of obstructions of the biliary ducts, has awakened a new and lively interest in all such cases, especially as the entire number of reported operations falls within a total of fifty. To this list Dr. Charles T. Parkes, of Chicago, in the July number of *The American Journal of the*

Medical Sciences, adds a very instructive case:

Of the cases submitted to operations, by far the larger portion has been of cholecystotomy, by means of which a distended gall-bladder has been positively relieved, and in most of them the cause of obstruction, retained gall-stones, removed. In a few no gall-stones were found, while in others the cause of the obstruction could not be remedied.

In Dr. Parkes' case the gall-stones were not lodged in the gall-bladder, and it is highly probable that they were retained in some of the dilated hepatic ducts, and were washed into the cyst by the flow of biliary fluid which came on immediately after the formation of the fistula. He is inclined to believe that they had but little to do with preventing the flow of bile into the intestine; at least the patulency of the passages was not restored by their removal. The remarkable and profuse flow of muco-biliary fluid, coming through the sinus established, argues very strongly in favor of the operation which contemplates the formation of a fistula in the gall-bladder in distension thereof by confined secretions. Certainly no tube of the dimensions of the ductus communis choledochus could have given a free exit to the secretions; at least, the accompanying back pressure on the walls of the cyst would have greatly endangered, if not certainly destroyed, the adhesions in any recent wound thereof, even when protected by the continued suture. Most of the cases of reported cholecystotomy tell of the presence of a freer flow through the fistula, so that it is a condition to be expected, and makes immediate closure of the bladder wound without drainage a dangerous proceeding to adopt, even if we can be positively sure of a clear common duct.

Dr. Parkes, in conclusion, advises from his experience in this case, the general practice of sounding the common duct through the external opening. He is quite sure that such procedure can be safely carried out, and equally certain that its adoption in his case resulted in relief that did not follow the removal of the calculi alone.

Treatment of a Form of Diarrhœa in Children.

Dr. James Braithwaite thus writes in the *Brit. Med. Jour.*, July 17:

There is a form of diarrhœa in children, usually occurring after weaning, and from that period to four or five years of age, which is characterized by the most horrible offensiveness of the motions. This is so marked, that it is generally at once mentioned by the parents. It is commonly met with in summer, but is not strictly what is known as infantile diarrhœa, in which disease the stools are sour, but not necessarily fœtid. Probably this form of diarrhœa differs from the diarrhœa of younger infants, in being caused by the growth of the ordinary bacteria of putrefaction. It is not amenable to treatment by any astringent, nor has any alteration of diet much effect upon it,

It may, however, be successfully treated by disinfecting the bowel contents by means of salicylate of iron, as in the following prescription, which is suitable for a child two years of age: Sulphate of iron ℈j; salicylate of soda ℈j; glycerine ʒiij; water to three ounces. The iron and the salicylate should be dissolved separately, and the solutions mixed. The color is darker than port wine, and the taste not unpleasant. One teaspoonful must be given every hour, until the stools become well blackened, which happens in about twenty-four hours; or a larger dose may be administered at longer intervals. The medicine should then be given every three or four hours, and occasionally a small dose of castor oil, to clear the bowels well out, and to get the secondary constipating effect of the oil.

I have employed this mode of treatment for many years. It was one result of a long series of microscopic observations upon the action of reagents upon the bacteria found in putrefying animal fluids, which I read before the Leeds and West Riding Medico-Chirurgical Society eleven years ago. The addition of the salicylic acid to the iron I made more recently.

In hospital practice, and amongst the poor, it is not so successful as it would be if it were possible to remove the child from the family living room, the air of which is usually very impure, and is made worse by the smells incidental to cooking, and the presence of a sink.

Electric Baths in Eye Diseases.

Professor Denti, writing in the *Annali di Ottalmologia,* states that he has found electric baths and douches very valuable in several ophthalmic affections, especially in those which refused to yield to more ordinary methods of treatment. His apparatus consists of a vessel of water placed at a height of two metres above the patient's head, a constant current battery of thirty

cells, and a glass or ivory box without a bottom. This box is fitted on to the eye. It contains a metal pipe communicating by an india-rubber tube with the water vessel, from which the box can be filled with water; an efferent non-metallic pipe is also provided. The metal pipe is connected by wire with one pole of the battery, the other electrode being placed on the forehead or crown of the head. The sittings are of from four to six minutes' duration. For baths eight or ten cells are used, for douches twenty or more. No unpleasant effects have ever been observed, the stimulating action being only sufficient to produce a slight degree of hyperæmia. The author finds that the baths are best in deep-seated affections, such as those of the vitreous or of the optic nerve; the douches are useful in more superficial affections, such as those of the conjunctiva and cornea. Dr. Denti tried the electric baths in six cases: four of atrophy of the papilla in different stages, one of disseminated cloudiness of the vitreous, and one of double ulcerative blepharitis. The papillar atrophy was benefited most when it was slightest. In one case of atrophy accompanying disease of the spinal cord, the intra-ocular affection was, or appeared to be, arrested. The patient with the cloudy vitreous was so much improved that, though at first he could scarcely distinguish large objects, after thirty sittings he was able to read ordinary print. The patient with blepharitis was completely cured. The douches were employed six times: in three cases of paralysis of the eye muscles, and in three of exudations remaining after ulcerative keratitis. One of the cases of paralysis was entirely cured, the other two being improved; and in the cases of keratitis the success was most marked, the exudation being completely absorbed.

Electrolysis for the Treatment of Urethral Stricture.

Before the Academy of Medicine in Ireland, Mr. P. J. Hayes read a paper on the treatment of urethral stricture by electrolysis, the comparatively novel method practiced by Drs. Robert Newman, of New York, and S. T. Anderson, of Bloomington. He gave the details of three cases, in which he had himself adopted the method with encouraging results. He strongly advocated the trial of electrolysis, even for the most complicated forms of stricture. It did not at all interfere with the subsequent employment of other measures, minor or serious. Electrolysis was best adapted for the treatment of annular strictures rather limited in length. Having ascertained the situation of the stricture, the tip or exposed metal bulb of an electrode ought, if possible, to be lodged within it; or, if this was impracticable, the tip must be in close contact with the anterior face of the stricture. Then a small galvanic battery was connected by its negative pole with the urethral electrode, whilst the positive might be attached either to a moist sponge electrode or, better still, to a thin metal plate covered with moistened chamois leather. The positive electrode would be advantageously applied either to the patient's perineum or against the inner side of one thigh. As to the strength of the current to be employed, the patient's own sensations would prove the best guide. The current should be perceived, but it ought not to be pushed to cause pain, nor should the surgeon attempt more than it was needful to effect at each sitting, using only mild currents, and manipulating the electrode with gentleness, and never pushing it through the stricture, as it accomplished more by being allowed to remain in the stricture than by being caused to quickly transverse it. The sittings might be repeated every ten days, if desired. Cauterizing would be produced when strong currents were employed; but, with mild currents, the gradual breaking up of fibroid tissue was effected by a combination of chemical decomposition and vital absorption until but a thin lamella of cicatricial tissue remained to mark the seat of the stricture.

Salicylate of Cocaine in Asthma.

A comparatively new method of treatment in asthma nervosum has lately been tried by Professor Mosler, of Greifswald. It is now well known that cocaine has not only a local action on the sensory nerve-endings, but also a central one, which at first stimulating to the nerve-centres, may, if the drug be pushed, become sedative, or even narcotic. By this peripheral or central effect, it may, therefore, act in such spasmodic diseases as asthma. Early last year, Beschorner published two cases of this disease which were much benefited by cocaine. In three cases, Professor Mosler has obtained excellent results. All these cases occurred in young people of twenty-three to twenty-five years of age, and were uncomplicated by any organic heart or lung disease. The drug was given subcutaneously, in doses of 0.4 gramme, at the commencement of the attack. The first patient, who had a bad fam-

ily history as regards lung disease, and in whom the asthma had lasted eleven years, was relieved after the third injection; two more doses caused abeyance of the attacks (which occurred previously every day) for a fortnight, when the patient was lost sight of. In the second and third cases, the treatment was more rapid in cutting short the attacks, which in the end were postponed for the three or four weeks during which the patients continued under observation. The injections caused, in one case, a slight sense of faintness, and the appearance of dark spots before the eyes; but these symptoms soon vanished. It is, of course, impossible to draw from these cases any conclusion as to the permanent benefit of the treatment. Extended experience will perhaps show that the drug is only a palliative. It is in the hope of inducing other practitioners to try the treatment that Professor Mosler has published the results of his cases.

Calculus in Women.

Dr. Wedensky, of Moscow, where stone prevails, has published in the *Vratch* some interesting statistical records of vesical calculus in women, as well as the results of his own experience. He notes that Hugenberger, after having examined 40,000 women for various diseases, did not come across a single case of stone. Winckel observed one case in 2,500 female patients. Sir Henry Thompson's statistics are well known in this country. Between 1808 and 1841, Bassoff, of Moscow, treated 2,989 cases of calculus, only 75 occurring in women. In the same city, Klin, between 1822 and 1860, had 1,792 cases, 4 being females. Twenty-five out or Mamonoff's 700 cases were women. Dr. Wedensky himself observed 980 cases in the Marien Hospital; 27 of these occurred in women. Thus, about 2 per cent. of cases of urinary calculus appeared in patients of the female sex. Lastly, the same surgeon has operated 29 times on females. In 3 cases the stone was removed by dilatation of the urethra, and all recovered. Dr. Wedensky prefers this method, done gradually on Simon's principle, when the stone is small. In 13 he performed lithotripsy; 2 of these cases died. He considers this operation by far the best method of treatment for large calculi, and, if the surgeon object to it, he recommends suprapubic lithotomy. In 3, Dr. Wedensky made a vesico-vaginal section, 1 dying. He objects to this plan, as being liable to leave a fistula. In 10 cases he performed lateral section, losing 3. He now rejects this operation entirely, as it leaves a troublesome and permanent cicatrix.

Dieulafoy on Bright's Disease without Albuminuria.

In a paper recently read before the Société Médicale des Hôpitaux (Paris), the author has described several cases of Bright's disease without albuminuria. The first patient was a woman, whose symptoms seemed to point to gastric ulcer. She had violent pain in the epigastrium and hæmatemesis; she also complained of constant headache, and was losing flesh gradually; the urine never contained any albumen; slight epileptiform attacks were followed by coma and death. At the post-mortem examination, the kidneys were found enlarged, and the microscope revealed the usual lesions of mixed nephritis. In the second case, the most characteristic symptom was a paroxysmal dyspnœa, which could not be explained by any lesion of the heart or lungs; there was a frequent desire to micturate, and the patient also complained of headache; the urine was scanty, but contained no albumen, except on the day which preceded the death; the necropsy showed that there was a well-marked inflammation of the interstitial tissue of the kidneys. Several other cases of a similar description have been observed by Dieulafoy, who concludes that the urine sometimes remains quite free from albumen in Bright's disease; this is especially the case when the lesions are more advanced in the vessels than in the glandular substance of the kidneys.

Chronic Abscess of Female Urethra.

Before the Obstetrical Society of London (July 7), Dr. Herman read a paper on a case of chronic abscess of the female urethra. The patient, aged forty-seven, had for four years suffered from dysuria, about two years from dyspareunia, and irritability of bladder, these symptoms gradually increasing in severity during this time. There was a tender swelling between the urethra and vagina. This burst into the urethra, pus being discharged. Examination with the finger through the dilated urethra eight days afterwards showed that the cavity was then about the size of half a walnut, with a soft, ragged, friable wall. Its interior was cauterized with nitrate of silver, and it soon contracted and disappeared. Four months afterwards the patient continued quite well. The author thought that there were two possible explanations of the origin of the abscess: 1. That

it was the result of chronic congestion of the urethra, such as that described by Sir C. M. Clarke. 2. That it was a suppurating cyst. Abscess from either of these causes was rare. He quoted three cases that he had been able to find recorded. He gave reasons for thinking that the abscess in his case was probably not a suppurated cyst, and that the case was therefore to be classed with those of congestion of the urethra described by Sir C. Clarke and Dr. West.

Lanolin as a Basis for Ointments.

In a preliminary note in the *Russkaia Meditzina*, No. 12, 1886, p. 207, quoted in the *London Medical Record*, Dr. L. K. Pavlovsky, of Kharkov, writes that his experiments with Liebreich's lanolin (first in Russia) enable him to arrive at the following conclusions: 1. Narcotic extracts, when combined with lanolin, are absorbed by the skin "quite satisfactorily," their pain-relieving action being obtained "with an almost perfect certainty." The dose used was only twice as large as that for internal use. 2. Hydrochlorate of quinine is absorbed also very easily. This statement is based on four cases of intermittent fever in children, where lanolin and quinine inunctions rapidly gave the effects desired. 3. When a lanolin ointment, with iodide of potassium, is rubbed in, iodine appears in the urine not sooner than two, four, or six hours after inunction, while Lassar obtained iodine from the urine about three minutes after friction. 4. In children, lanolin is better absorbed than in adults. 5. Washing the skin with ether considerably facilitates the absorption of lanolin ointments. 6. In general, lanolin is a substance which promises to supersede all other constituents for ointments, and even, in certain cases, to render superfluous the internal use of drugs.

An Instance of Seemingly Unusual Susceptibility to Ether.

Dr. George W. Squires, of East Avon, N. Y., reports the following case to the *Med. Record*, July 24:

Mrs. W., forty-five years of age, housewife, fell down stairs, striking her face against the railing, from which she sustained quite a severe contusion of the right cheek, with effusion of blood under the conjunctiva, from the outer canthus to the margin of the cornea. When first seen she was suffering from a slight frontal headache, for the relief of which the writer applied to the forehead not more than six or eight drops of sulphuric ether with a camel's hair brush. The patient at once said, "That is ether, and it is putting me to sleep," and in less than half a minute she was fully under the influence of the anæsthetic, remaining unconscious for several minutes, and upon recovery, and for some time afterward, presented all the symptoms following profound and prolonged etherization. She could not have inhaled more than three to five drops of the ether, as it was immediately washed from her forehead.

Acetate of Copper in Pulmonary Diseases.

M. Luton recently communicated to the Academy of Medicine of Paris a memoir on the therapeutic use of acetate of copper, principally in pulmonary tuberculosis. He prescribed this salt in a daily dose of 1 centigramme, which was mixed with 25 milligrammes of extract of opium. In this form it was perfectly tolerated by the patient, and produced sleep. The pills were taken in the evening. Under the influence of acetate of copper, M. Luton had seen cough, expectoration, high evening fever, and nocturnal perspirations diminish. At the same time, the stethoscopic signs revealed an amelioration of the pulmonary lesions, but the appetite did not improve. M. Luton thinks that the hectic fever of phthisis had given place to a continuous fever of an infectious nature. He also considered this action to be parasitic and specific; but his colleague, M. Poncer, regarded the salt as a tonic and stimulant.

Anderjou.

Anderjou, or Anderjoa, or Indurjuo, is the seed of the *Holarrhena antidysenterica* described by Waring ("Pharm. of India," 1868, p. 137). Its bark was formerly imported into Europe under the name of *Codaja pala*, pala bark, and Tellichery bark. It seems to have fallen into discredit in consequence of being mixed with barks of other species. But it is still used very extensively in the island of Mauritius as an anti-dysenteric remedy, especially in the form known as "remède Mauvis." According to information given in the *Bulletin de la Société Médicale de l'île Maurice*, this remedy is prepared as follows: Take one pound of anderjou, clean, dry, and crush it. Take twenty spoonfuls of this powder, and mix intimately one spoonful of a combination of roasted anderjou with arrowroot. Divide into doses of about 6 drachms each, and take one daily, infused in about 16 ozs. of water.

The Treatment of Stricture.

In my own practice it is my rule immediately (says Dr. David C. Bryan, in the *Med. Herald* for July) on commencing to treat a case of stricture, to prescribe elixir thion compound, teaspoonful three times a day before meals for my patient, and to continue this medicine throughout the entire case. This remedy has never failed in my hands to thoroughly alkalinize the urine, to keep off rigors, and seems to have a specially relaxing effect on the tissue. When there is a false passage, put your sound in it, and pass a small filiform bougie down by its side; usually it will find the true orifice. Whatever method is tried should have a fair trial. Fickleness may result in failure.

Mammary Neuralgia.

At a recent meeting of the Paris Surgical Society, M. Routier read notes on a case of intense mammary neuralgia. The patient was 22 years of age; a small tumor, the size of a nut, was removed, and the pains completely disappeared. On microscopic examination, the tumor presented the characteristics of an adenoma.

Correspondence.

A Case of Disease.

Eds. Med. and Surg. Reporter:

A case of cerebro-spinal meningitis published by Dr. Albert Wilson in the *Brit. Med. Jour.*, of April 12, 1844, and republished in the Reporter, June 7, 1884, was reviewed by me May 16, 1885. I was impelled to review it in the hope that a careful analysis of his treatment and a fair presentation of its inefficiency, to say nothing of its danger, might save some valuable life. There was another reason for my noticing it. Three months before his case was copied by the Reporter I had successfully treated a case more violently and suddenly attacked, by very different means—means not at all popular, but more comfortable to the patient, and more likely to avert the expense of a funeral, a matter of some importance to people of moderate means. When my review was published, it was my intention to give your readers a report of my case, and for that purpose wrote it out carefully. Though it has been laid aside for a whole year, circumstances have taken place which induce me to offer it to you. I may premise, for those who have not read Dr. Wilson's case, or my review, that his treatment was confined almost exclusively to the steady, persistent use of bromide ammonium, chloral, and at last iodide ammonium. There were given 420 grs. bro. am., 40 grs. chloral, and 20 grs. iodide ammonium in 36 hours, and that, despite the fact, as observed by him, that they "produced no soothing effect." The man was sick 48 hours, being unable to take the medicine during the last 12 hours. My case is as follows:

At one o'clock a. m., March 4, 1884, I was called to see Lizzie Samson, aged eleven years. As I had not visited any one at night for quite a long time, I asked for a history of the case, hoping that I might send something for her relief. The father said: "Lizzie was as well as usual last evening at 8½ o'clock. I then went to the barn to see that everything was right, and had been out but a few minutes, when I was called and told that she was very sick. I found her on the floor holding her face between her hands, and screaming with pain. Since then her pain has been violent. She has vomited much, and is now vomiting blood." He was so exceedingly anxious and distressed, the case seemed so unusual, and as I had attended all his children on all occasions of sickness, and was fully awake, and the night pleasant, I went to see her. Found her holding her head by a hand on each side over the temples, moaning piteously, face very pale, pulse 80, beat indistinct—by that I mean that it required close attention to count it. Some persons would have called it feeble. She lay with her eyes closed, but on opening them they seemed to be natural in size of pupil. The mother said, "she had played actively in the meadow before dark, and was apparently well during the evening, but suddenly, just before her usual bedtime, cried out, with a scream, that she had pain through her forehead, and instantly went prone on the floor. That there had been no relief since that time—then five hours after the attack—that everything she had taken had been instantly vomited, that she was dull, indisposed to answer questions, and every few minutes cried out with pain, and then relapsed into her semi-conscious condition."

On examining the fluid which she had vomited, and which they had believed to be blood, I found it a dark flocculent fluid, resembling coffee-grounds in color. I was uncertain what to do, because I did not know what was the matter with the child. It seemed from the vomiting of this dark fluid that she might be suffering from irritation

in the stomach, but as the severe pain in the head was the first symptom, I concluded to regard the brain as the seat of disease. And then morpheum to relieve the pain suggested itself, but I feared to give it without further observation of the case, and also lest the anodyne, while it might overcome somewhat the pain, would add to the dullness, so that I could not say whether the symptoms were from the disease or the remedy. I therefore had iced water put on her head, warmth and irritants to her feet, which were quite cold to my hand; ordered bro. pot. gr. x every two hours until my return, which I intended should be very soon. It was then 4 a. m. of the 12th. At 8 a. m. saw her again. She had vomited instantly after swallowing drink or medicine, and the pain in the head was so severe as to cause her to cry out frequently, and she was even duller than before, and more reluctant to reply to questions; still very pale, pulse from 80 to 90, but indistinct, some of the beats being readily felt, others scarcely perceptible. Sometimes, in cases of sickness of stomach connected with disease of brain, it is difficult to tell which is the primary affection. With me it was so here; but the severe and persistent pain in the head inclined me to locate it in the membranes of the brain, though the pale face, the condition of the pulse, and the integrity of the mind, made me doubtful. As she had been sick only twelve hours, I directed 5 grs. bro. pot. and as much bro. sod. every two hours; two bladders of ice and water to be applied on the head so as to cover it all over, the nurse being urged to keep it continuously applied. Saw her again at 1 p. m.; no change. Saw her again at 6 p. m.; duller, moaning, screaming now and then with pain; pulse 80, indistinct as before. How glad I would have been to call to my aid one of those skilled neurologists who know the exact position of every centre, have names for and know the functions of every convolution. I would have asked him why this great paleness, this unusual pulse, this pain in the forehead, this nausea and vomiting? Where is the primary affection? Is this great pain merely a neuralgia, or was there a sudden congestion? And if so, would a congestion produce so quickly a pain so violent and so unremitting? Would it too produce vomiting and dullness of the intellect? Still more would it have comforted me to have been informed of the cause of another symptom noticed by the family to-day, and to which they had just called my attention, and the significance of which they desired to know. On raising the child's head from the pillow, it would fall about as if there was not a single bone in the neck. I raised her by putting my hand over the last cervical vertebra; her head fell backwards as though she had not the least control over it. I raised the body to a perpendicular with my hand behind the head, it fell forward on the breast; leaned slightly to one side, the head fell over as though there was nothing to support it. When put on the pillow again, she seemed to have her head under control. At first I thought it probably caused by faintness from being raised; that it was not, good evidence was given as the case progressed. It would then have comforted me greatly to have been enlightened in relation to this symptom. To me the nervous system has been a lifetime study. Securely housed within the cranium and vertebra, with entire control of the most sensitive telegraphic communication to and from every part of the body, not a sight, or sound, or taste, or touch, or odor, but is instantly recognized, and its influence on the system manifested. Every movement of all parts of the body is under the control of the nervous system. It directs the action of the heart, presides over every function, regulates the vital chemistry of every molecule so as to produce the vital heat, without which life cannot be preserved for a single moment. How important then that we should read its disturbed manifestations aright, and be ready to correct them. In view of its great importance the query arose, what is the cause of this condition of the child? Why this changed, apparently enfeebled action of the heart? Why this refusal of the stomach to take its ordinary food and drink? Why this strange loss of power in the muscles of the neck, and this dullness of intellect, all so suddenly presented? Are all these caused by malaria, a name for something never yet detected? Are there germs in the blood, bacteria? If so, have these germs suddenly become virulent, and gone on the war-path, after being with her all her life and behaving themselves well? Will they now, like yeast in a mass of flour, multiply and spread themselves through every tissue, block up all the avenues in the brain, permeate its substance, and thus destroy life? Or has "septic material" which had been floating in the air, been taken into the system, and is it now corrupting her blood and weakening and disturbing the nervous system, and through it the body?

(*To be continued.*)

—That well ventilated bed rooms will prevent morning headaches and lassitude.

News and Miscellany.

Anatomical and Medical Knowledge of Ancient Egypt.

In the *Lancet*, July 17, we read as follows:

The surviving fragments of the early literature of Egypt are mainly of a religious character; but this is not to be wondered at, for the genius of the people was essentially religious, and their doctrine of the future state leavened their national life in almost every particalar. To them the body was an integral part of the immortal humanity; therefore it could not be permitted to turn to decay, but had to be preserved from corruption that it might be a fit receptacle for the soul to dwell in through eternity. Their treatment of the body was thus dependent on their belief of its relation to the soul, and this, we learn from their religious writings, was a relationship of eternal interdependence. To secure perpetual preservation the body had to be properly embalmed, the cavities opened and subjected to the action of antiseptics. Although the body was sacred, under the special protection of the god Thoth, though each part was under the guardianship of a special divinity, yet this sacredness did not preclude careful inspection and the processes necessary for preservation, for all parts had to be perpetuated. Embalming was a religious rite, to be performed by the priests of the Cultus; and the historian Herodotus has preserved for us what is doubtless a substantially accurate account of the different methods whereby it was done in the later times in which he lived. The organs removed from the bodies of persons of the better classes were not returned into the body, but were preserved in vases of alabaster or stone, surmounted by the heads of the four divinities of Hades, the sons of Horus and Isis. The vessel which contained the stomach and colon bore the human head of Amset; that which held the lungs and heart was under the protection of the jackal-head of Tuaut-mutef; that which contained the small intestine was beneath the baboon-head of Hapi; while the liver was guarded by the hawk-head of Kabhsenuf.

During the ascendency of Greek influence in Egypt, Alexandria earned the reputation of being the chief school of anatomy and medicine in the world. Erasistratis, who lived in the days of Ptolemy Soter, B. C. 285, was an anatomist of such enthusiasm, that he and his disciples receiving from the king criminals condemned to death, "Vivos inciderint considerarintque etiam, spiritu remanente, ea quæ natura ante clausisset, eorumque posituram, colorem, figuram, magnitudinem, ordinem, duritiem, mollitiem, lævorem, contactum, processus deinde singulorum et recessus et sive quid inseritur alteri sive quid partem alterius in se recipit." But this Alexandrian school, although upon Egyptian soil, was essentially Greek in spirit; even Herophilus had learned some of his anatomy from Praxagoras of Cos, although, as the anatomy of the earlier Greek school was originally derived from Egypt, it was but returning to the mother country the traditions of culture derived therefrom. It was in Egypt Democritus of Abdera studied and so was fitted to teach anatomy to Hippocrates, the father of medicine. The three pithy and graphic letters on anatomy (which are extant), which it is supposed Democritus sent to Hippocrates, may well have been the result of his Egyptian training. At a later period, it was at Alexandria that Galen pursued his study of anatomy under Heraclianus, and the anatomical school of Alexandria survived until the Mohammedan invasion of Amru in A. D. 640. That much even of the earlier Greek medicine, anatomy and pathology was derived from Egypt, we learn both directly and indirectly. Most of the vegetable drugs in use in Greece were natives of Egypt; and Galen, speaking of one prescription called Epigonos, tells us that it was obtained from the adytum of the temple of Phtah, at Memphis. He quotes it, and other Egyptian prescriptions, from the book Narthex, written by Hera of Kappadokia. Medical colleges of far greater antiquity than that of Alexandria existed in the priestly schools of Memphis, Heliopolis, Sais, and Thebes. These were much more faithful exponents of the purely Egyptian system of the art of physic. Of the ancient medical literature of Egypt, two nearly complete treatises are still extant, and six or seven fragments of others. These vary in date and in perfection. The most complete are the Papyrus Ebers and the Medical Papyrus of Berlin. The fragments which are noteworthy are: The British Museum Papyrus, formerly the property of the Royal Institution, the Papyrus VI. of Boulaq, the Magical Papyri of Turin and Paris, the Coptic Medical Manuscript in the Borgia Library, and the Greek Papyri 383 and 384 of Leyden. In a paper read at a recent meeting of the Royal Institution of Great Britain on the Medical Knowledge of Ancient Egypt, of which the above is a summary, Professor Alexander Macalister, M. D., F. R. S., stated that he hoped soon to be in a

position to publish a detailed and critical study of this medical literature, a work for which few are better qualified.

Quackery in French Religious Communicants.

The *St. Louis M. and S. Journal* for July tells us that in a little commune of the Vendèe, near the borders of the Department of Deux-Sevres, a rural school-house shelters five or six *religieuses*. The government some time ago ceased to give them any support, so that it became necessary for them to look about for some other means of living and keeping the wolf from the door. After looking around a little, the good sisters determined to make some money out of their knowledge of the medicinal value of the herbs and simples around them, and which had hitherto been applied to the gratuitous healing of the ills of their neighbors. It seems that in some manner they had acquired a reputation for curing the goitre, and not long ago a peasant living some distance from them undertook a journey to their establishment in order to obtain from the charitable sisters the remedy for a goitre which disfigured his spouse. They gave him a box of pills and received in return six francs, and the peasant went on his way rejoicing. As luck would have it, however, the sister who was called to accompany him to the gate and let him out, inadvertently displayed the fact that she was herself afflicted with a great goitre. The patient was sharp enough to see the point, and immediately began to bellow that he was robbed. Not getting his money back, he complained to the authorities, and thus the matter stands. It has, however, served to call attention to the fact that religious communities all over France are doing the very same thing, and not only this, they are using the knowledge and facilities thus afforded them to the great detriment not only of the medical profession, but of the Government itself. Most of these communities are violently anti-republican in their sentiments, and devote their entire time to the quiet *propaganda* of monarchical and clerical ideas. This fact once brought home to the authorities ensures their suppression.

Charms and Superstitions in the Treatment of Diseases.

The *Brit. Med. Jour.* says that the Bishop of Bedford is quite at home among the people, and knows them in sickness and in health. He gives some curious examples of the still prevalent superstition as to charms against sickness, which are worth preserving among the records of medical folk-lore.

For many years he labored in a country parish in Shropshire, and the remedies believed to be efficacious in many complaints absolutely surprised him. In cases of whooping-cough, for instance, a woman would send children suffering from it along a towing-path of a canal to meet a certain boat, the reason being that the boatman was a seventh son, and any remedy suggested by a seventh son would, it was thought, do good. Another popular remedy was to pass children over and under a briar seven times; another horrible thing was to draw three yards of black ribbon through the body of a frog, and wear it round the neck; and another thing was to make a child breathe into a frog's mouth. It was supposed, too, that anybody riding on a piebald horse could cure whooping-cough. He had seen a woman pretending to charm away a tumor on the lips of another woman with elder-pith which was got at night under a full moon, and by the use of some words which, the charmer said, were in the Bible, but on being told that they were not, said she was sure they were in the prayer-book, and this was equally incorrect. A farmer, who had the toothache, had given to him some gander's teeth to put in his waistcoat pocket. These were only a few of the superstitions that had come under his notice in North Shropshire, and perhaps some of our readers can add to this curious budget of surviving superstitions.

The International Medical Congress.

"A well-known American physician writes to us from Berlin, under date of June 30, that he has lately come in contact with prominent members of the profession in that city, Bremen, Hamburg, Dresden, Munich, Vienna, and Breslau, and that everywhere the leading questions were: 'What about the Congress of 1887? Will it be held? Will it be a success? Will you be there? How much reduction will there be in the passage rates? Is it to be managed by homœopaths? Have the dissensions which threatened to wreck the Congress been adjusted? Whom shall we meet whom we know?' etc. To these queries he felt it his duty to answer: 'The Congress will surely be held. Whether it will be a success cannot now be foretold. I shall not be there. So far as I know, there will be no reduction in fares to America. The homœopaths have nothing whatever to do with the Congress. The dissensions have

not been adjusted in any sense whatever. You will be likely to meet chiefly men whom you do not know by name or fame, since the majority of the best known men in the United States have withdrawn from the Congress because they do not approve of the way in which it is managed.' 'With but few exceptions,' he adds, 'I found very little inclination to incur the trouble and expense of a trip across under such discouraging auspices. My replies only corroborated previous impressions.'"

The above is from the *N. Y. Med. Jour.*, July 24. We must say that out of respect for the profession of the United States, the *anonymous* correspondent of the *N. Y. Med. Jour.* ought to have been ashamed to write such "*reflections of his own wishes*," and the journal ought to have been ashamed to publish them.

A New Use for Carbolic Acid.

A new use for carbolic acid has been discovered by an Australian inventor, namely, for tanning leather. We had thought that Australia affords more than enough natural tanning material without this invention. In the process the skins, which have been limed in the ordinary manner, also haired and prepared if for the production of sole leather, are placed in a bath consisting of a mixture of tens gallons of water in which 200 pounds of soap are dissolved, and containing one gallon of carbolic acid, the skins being left in the bath until tanning is complete. The process may be considerably accelerated by adding a pint of fresh carbolic acid to the tanning fluid from time to time. For a softer leather the raw, limed, and haired skins are for one or two days placed in a mixture of four parts carbon bisulphide and one of carbolic acid, and then washed.

Lard.

At a recent meeting of the Philadelphia Pharmaceutical Association a member asked what was the usual practice in reference to lard for pharmaceutical uses, and what was found best. A member stated that he had lard made in the country specially for him, and found it entirely satisfactory. The inquiry was made whether the refined lard of commerce was pure enough for medicinal purposes; this was answered that one of the houses who refined very large quantities of lard stated that they made none at all, but merely refined it. It was queried, What percentage of water was present in commercial lard? but no one present stated that they knew what amount of water it did contain. The preservation of lard by means of benzoin and poplar buds was also discussed, and some thought that benzoic acid would answer as well as benzoin, while another present expressed the opinion that the resinous matter of the gum benzoin was the efficient agent.

Cholera Prospects in Paris.

A Paris correspondent telegraphs: "In consequence of the exceptional heat, and the increased consumption of spring water, the municipal reservoirs in which it is stored are well nigh empty. The municipality is, therefore, obliged to discontinue its supplies to several arrondissements. The water which is to be given instead will be taken from the Seine above Ivry." This information is justly disquieting. It may, and certainly should, be remembered that the last outbreak of cholera in Paris was traced to the temporary distribution of contaminated water under similor circumstances. The inhabitants of Paris should protest; and, meantime, visitors should be on their guard. The last epidemics, not only in Paris, but in London, Geneva, and Naples, were distinctly traceable to the water supply.

Antiseptic Paper.

Dr. Bedoin, of the military hospital of Vincennes, makes light, cheap, and effective applications for wounds by using instead of gauze, unglazed paper (filtering or cigarette paper) first sterilized in a drying cupboard at 110° C., then rendered antiseptic by immersion in a solution of carbolic or boric acid, sublimate, etc. This can be used in layers or plugs, and is covered with thin sheets of gutta-percha.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE WEEK ENDED JULY 24, 1886.

Carmichael, D A., passed assistant surgeon. Granted leave of absence for thirty days, July 24, 1886.

Magruder, G. M., assistant surgeon. To proceed to Cairo, Ill., for temporary duty, July 22, 1886.

The Perfect Druggist.

This gem we cut from the presidential address of the Virginia Pharmaceutical Asso-

ciation: "There never has been a perfect druggist, and there never will be. The science of pharmacy is more or less connected with all the natural sciences, and a perfect acquaintance with them is very rare. A good pharmacist should thoroughly understand the principles of his profession as well as the responsibilities of his business, and he should have a good practical experience in all its details, without which technical knowledge does not amount to much."

Galvanic Flannel.

A novel method of applying an electric current to the body forms the subject of a patent granted to the agent of Señor Pumariega, of Avile, Spain (2,322, 1886). The inventor steeps flannel in a bath composed of equal parts of oxide of iron, copper, zinc, and tin, mixed in fine powder in weak gum-water. The flannel thus takes up a quantity of the metallic oxides which are excited by the perspiration of the body, which is then subjected to a weak but constant electric current.

Items.

—Piliganine is the name which has been given by M. Adrian to a new alkaloid which he has isolated from *Lycopodium saussures*. It has an alkaline reaction, and emits white vapors, like ammonia, in the presence of hydrochloric acid, and therefore appears to be of a volatile nature. It causes powerful emesis and catharsis.

—"The Effects of Tobacco on the Health of Men of Letters, and its Influence on the Future of French Literature," is the theme to be discussed in a series of essays, for the best of which the French Society for the Prevention of the Abuse of Tobacco offers a prize of 1,000 francs.

—It has been objected against eserine that it increases the intra-ocular pressure whilst contracting the pupil; pilocarpine, on the other hand, is said to lower the intra-ocular tension. These myotics have been set against one another in the treatment of some cases of glaucoma. Schlegel has made some experiments on the intro-ocular tension, and arrives at the conclusion that the alkaloid of jaborandi also increases the tension.

—From Saturday, July 17th, till Wednesday, July 21st, the following are the reported cholera returns from Italy: Brindisi, 28 cases and 11 deaths; at Francavilla Fontana, 66 cases and 15 deaths; at Latano, 37 cases and 14 deaths; at San Vito, 20 cases and 3 deaths; at Oria, 2 cases; at San Donaci, 4 cases and 2 deaths; at Venice, 2 cases and 2 deaths; at Codigoro, 10 cases and 2 deaths; at Erchie, 2 cases and 1 death; at Ostuni, 5 cases and 1 death.

—The *Madrid Medical Journal* of July, 1885, reports that Miss Dolores Lleonart-y-Cassanovas, daughter of Dr. Agnew Lleonart, has just obtained, by unanimity of votes, her M. D. degree at the Barcelona University, after passing a brilliant examination. Miss Lleonart commenced her studies at the age of 8, got her B. A. degree at 13, carried off seven prizes and the highest marks in every examination, and now, at 19, her full degree in medicine and surgery. It would seem that ladies mature early in Spain.

QUERIES AND REPLIES.

Information Wanted about Antipyrin.

Eds. Med. and Surg. Reporter:

I desire to trouble you for a little information in regard to "antipyrin." I have read a good deal about it in the journals, but as I do not know the writers, and am unwilling to take anyb dy's dictum for granted, I desire to ask you, and upon what you say I am willing to act without hesitation. Is it of any practical use, save to reduce, *rapidly*, temperature, and for that purpose is it *safe* and *reliable?* Is it a better febrifuge than aconite and nitre, with potass. bromide or soda bicarb.? My favorite fever mixture is:

℞. Tr. aconite root,	gtt. viij.
Spirits nitre,	℥ij.–iv.
Sodæ bicarb., or pot. brom. p. r. n.	
Water ad.,	℥j.

A teaspoonful in water every half hour or hour.

In our remittent fevers, with marked congestion, the above answers well, and though slow, yet the action is permanent and entirely safe. Do you think antipyrin would do better?

We often have patients with a temperature from 104° to 105° F. Give a strong mercurial purgative, say in three doses at intervals of three hours, every half hour or hour give the above ℞., and sponge with cold or tepid water, and in from four to ten hours the temperature comes down to say 101° or so. Then give *full* doses of quinine, 10 grains every two hours till well impressed, and our patient is safe *almost invariably*. If you would advise antipyrin, in what dose and at what interval repeated?

Let me state a case I had last week. A lady was confined at five o'clock Wednesday morning; did remarkably well till Friday morning; at 8 o'clock had a severe rigor, followed by a fever; temperature 105½°, and remained so till 2 o'clock Friday night. There was great tenderness of abdomen and some tympanitis. Patient was stupid, but there was very little delirium, no nausea, and no diarrhœa; the breasts, too, were full, hard, and tender. I gave a good calomel and rhubarb purgative and the above fever mixture every half hour, and then every hour. Applied cold water to the head, which was aching badly. At 2 o'clock p. m. the thermometer marked 102½°. Gave at once 8 or 10 grs. quinine, and repeated the dose in an hour, and then in an hour again. In this time the temperature had come down to 100°, patient sweating freely. By 8 o'clock the bowels moved well, and temperature was normal and so remained. There was no more exacerbation.

Now, in such a case, would antipyrin have answered? Would it have reduced the temperature quicker, and if so, would it have done to give the quinine as I did? I know quinine is given in large doses as a febrifuge, but *unless the fever is going down when given, it has always failed in my hands.*

We have very many cases like this. A child from three to ten takes a chill, goes into a stupid condition from which it is impossible to rouse him. Cannot swallow, though pulse is good; temperature 103° to 106°. Now, could antipyrin be used efficiently with the hypodermic syringe, and in what dose? I usually pour cold water on the head and sponge the body. Give a strong enema, and as soon as the patient can swallow give the mercurial boldly, and then follow much the same plan as in the case I described above, and I don't know that I ever lost a case.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infections and disease-producing matter.

INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,
36 Platt St., New York.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful Home.

R. A. GIVEN, M. D.,
BURN-BRAE, CLIFTON HEIGHTS, DELAWARE CO., PA.,

Assistant Physician,
J. WILLOUGHBY PHILLIPS, M. D.

Lecture.

ON HYGIENIC THERAPEUTICS.

A CLINICAL LECTURE BY DR. DUJARDIN-BEAUMETZ,

Member of the Academy of Medicine, Physician to the Cochin Hospital, Paris, France.

(*Concluded from page* 164.)

The precepts of this school were altogether hygienic. Numerous translations have been made of this famous medical doggerel. The most remarkable, certainly, is this which I here show you, and which was published in 1661, by Dufour de la Crespeliere. Like the original, this translation is in verse.

Our medical confrere was a wag something after the style of Rabelais, and the modern epithet of *naturalistic* is applicable to his verses. [Several couplets quoted by the lecturer are omitted as being untranslatable into English.]

Then for a long period of time nothing more was heard about therapeutic hygiene; but few men in the practice of medicine were hardy enough to oppose the gross empiricism which then directed the art of healing. Among the independent spirits of that epoch we see Mercurialis rehearsing all the advantages which the ancients derived from gymnastics, and Cornaro, in his celebrated work on the Art of Attaining Long Life, showing the benefits which, as promoting longevity, flow from sobriety and a careful regimen. Sanctorius also by his remarkable experiments on himself brought into clear light the important role which in the functions of the economy belongs to cutaneous transpiration.

But all these attempts proved barren of fruitful results, and medical practice continued to follow the path mapped out for it by the chemiatric and iatro-mechanical notions of that epoch. The greatest abuse was made of drugs, and the aphorism in all its rigor was applied to the treatment of the sick: "To grave disorders belong powerful remedies." As proof of this, you have only to glance over that curious journal "Of the Health of Louis XIV.," kept from 1647 to 1711 by the three physicians-in-chief of his majesty, Vallo, Daquin, and Fagon, and you can but notice the innumerable quantity of purgings, lavements, bleedings, and drug-dosings, which this monarch was made to endure. We find here a complete justification of the ridicule of Molière, and the medicine bills of the apothecary Fleurant are mere bagatelles in comparison with the extravagant drugging which was then practiced in the chambers of our kings.

The first effective opposition made against the abuse of drugs is to be credited to the English physicians. Sydenham, in calling back his contemporaries to observation and experience, in showing the influence of atmospheric conditions on the production of epidemics, gave to medicine an impulse favorable to the study of hygiene. Gideon Harvey, a descendant of the discoverer of the circulation of the blood, and physician to Charles II. and William III., pushed to the utmost length his abhorrence of the extravagant dosing of that period, and he boldly advocated the substitution of the culinary art for pharmaceutical measures in their treatment of diseases.

These views received support in Germany in the eighteenth century from Stahl, who following the teachings of Sydenham and

Harvey, maintained that as a great number of diseases undergo a normal evolution towards recovery, attention to hygiene alone suffices for their cure, and in a work dated 1730, and having for its title "The Art of Healing by Expectancy" he sets forth his views on this subject. Cheyne, in France, a Jansenist physician, Dean of the Faculty, adopted the views of Harvey and Sydenham. He combated especially alimentary excesses, and endeavored to show that most diseases depend on abuses of eating and drinking. He therefore recommended severe dieting, a vegetable diet and milk; and he published in 1724 a treatise on hygiene applied to therapeutics which had for its title "*De Infirmorum Sanitate Tuenda Vitaque Producenda.*"

But all these writings of the eighteenth century have almost passed into oblivion, and we have to come down to our own times to see a revival of hygienic therapeutics. Three men were the chief promoters of this reformation: Ribes, Fonssagrives, and Bouchardat.

Ribes, professor of the school at Montpellier, in a volume which may still be consulted with advantage, established the basis of hygienic therapeutics.

Fonssagrives continued the work of Ribes, and in numerous treatises on hygiene, and in particular in his treatise on alimentary hygiene, he showed what may be accomplished by regimen as a therapeutic means.

Finally, my regretted master, Bouchardat, whose recent death is such a loss to the medical profession of France, in all his writings has urged the importance of hygienic therapeutics, and I cannot do better in this connection than quote the following sentences which terminate an article on the subject:

"I have experienced two distinct phases in my career as a medical practitioner. I devoted a part of my younger days to pharmaceutical therapeutics, and my riper years to original researches on hygienic therapeutics. Young physicians will find, as I have done, as they advance in years, that pharmaceutical therapeutics does not keep all its promises, and they will have more and more faith in a sage reliance on hygienic modifiers." No more just remark could have been made.

Hygienic therapeutics is then that part of medical science which has for its object the employment of hygienic modifiers in the treatment of diseases, and the regulation of the conditions thereof in such a way as to lead with the greatest possible speed and certainty to the recovery of the health. Formerly to this aggregate of means the name *dietetics* was given, but the use of this word is now restricted to alimentary hygiene.

This definition, which I borrow from Bouchardat, seems to me an excellent one. It enables us to establish the limits of hygienic therapeutics. In fact, if we were to include under the term hygienic therapeutics all the means proper for the maintenance of health, we should have to make the word synonymous with hygiene itself; but we are here concerned with the sick man and not with the well man, and we have to limit the significance of the term to all such measures, daawn from hygiene, as are applicable to the treatment of disease. We must also exclude from our definition everything comprehended under the definition of *prophylactic treatment*, a kind of treatment which is absolutely hygienic, but which is addressed to persons that are well, for hygienic therapeutics includes only such hygienic means as are calculated to combat disease and restore health.

I shall leave then to one side everything which concerns international hygiene, boards of health, quarantines, civic hygiene, etc., in a word, all those measures which play a considerable part in the prophylaxis of contagious and infectious diseases, but have nothing to do with therapeutic hygiene properly so-called.

It will not do, however, to confound expectant medicine, or expectancy, with hygienic therapeutics. Expectant medicine is a negation; it is showing respect to the normal tendencies of disease and letting it alone, while hygienic therapeutics essays to act energetically and surely in the treatment of diseases, and we may say that there exists a great number of affections in which the whole treatment is summed up in a well directed hygiene. See how it is in certain affections of the stomach, and in particular in ulcer of the stomach, in which milk diet is the only curative agent. Glycosuria can hardly be treated except by a judicious alimentary regimen and by muscular exercise, and in albuminuria it can scarcely be said that we have any effective remedial agency but regimen. The therapeutics of early infancy is in great part hygienic, and in the case of these frail and delicate little beings, disease generally results from infractions of the rules of hygiene, and finds its remedy only in means that are, properly speaking, physiological.

Moreover, the valuable discoveries of Pasteur, and those still more recent of my friend Armand Gautier, give to this question of hy-

gienic therapeutics a vital importance. In showing us the living nature of contagium in virulent and infectious diseases, in demonstrating the presence of morbid germs in the air which we breathe and in the water which we drink, Pasteur has given us a striking proof of the necessity of hygiene in opposing these communicable diseases.

If the microbiotic doctrines have overthrown many theories connected with therapeutics, they have on the other hand demonstrated the utility of hygienic practices. It is above all in modifying the culture medium, and in rendering it unfit for the development of microbes, that we are able to combat a great number of diseases. See, for example, how it is with phthisis: its contagiousness is admitted by all; Koch has even shown us the cause of this contagiousness. We know the energetic resistance which the tubercle bacillus presents to antiseptic agents; we know, too, that in our hospital wards we are surrounded by the micro-organisms of tubercle. How is it that we resist their invasion? Because our organisms constitute for them a soil unfit for the culture of these proto-organisms, and hygiene is one of the most powerful means for the creation of such refractory media.

The doctrines of Bouchard and Gautier show also the importance of the question with which we are concerned. The living cell secretes at each moment toxic products which the economy has to eliminate by its different emunctories. The rôle of the hygienist is here marked out; it is his duty to favor the physiological functions of these different emunctories, so as to oppose the retention of these morbid products.

Do not think, gentlemen, that I advocate following an exclusive course, and that I would abandon pharmaceutical means in the treatment of disease. I believe more than ever in the utility of medicines.

But I am convinced also that physicians are too apt to forget that by the side of these active medicinal agents there are other agencies of equal efficacy, which are entirely borrowed from hygiene. It is to the sum of these means that I desire to call your attention, and I hope to show you in the course of these lectures the utility of the subject of which I propose to treat.

For the accomplishment of our task, two methods are open to us. According to one plan we might take up in their order the diseases of the different systems of the economy, then pass in review the hygienic agents proper in the treatment of these diseases. We should study in this way successively the hygiene of diseases of the heart, of diseases of the lungs, of the stomach, etc. The other plan consists in examining separately each of the great hygienic agencies—alimentation, aeration, exercise, etc.—and investigating the rôle which belongs to each of these in the treatment of diseases. It is this last method which I have adopted. It enables one, in fact, to study in a general manner the physiological rôle of each of these great hygienic agencies, and derive therefrom practical clinical applications.

In the next lecture I propose to take up alimentation and its application to the treatment of diseases.

COMMUNICATIONS.

ON THE PATHOLOGY OF SURGICAL INFECTION AND THE VALUE OF ANTISEPSIS.

BY A. H. P. LEUF, M. D.,
Pathologist to St. Mary's Hospital and to the Hospital for Nervous and Mental Diseases, Brooklyn, N. Y.

(*Continued from page* 169.)

The views of Brehmer* are here worthy of consideration. After painstaking clinical observations and post mortem studies, he concluded that it was the rule for those who died of phthisis to have been predisposed to it; that the predisposition was mainly due to anatomical causes; and that these causes could be mitigated or entirely eradicated. His views were announced to the profession of Germany, and received with incredulity and much adverse criticism. The opposition came from the most eminent. He challenged their right to denounce his views without a special experience equal to his own, and agreed to re-open the discussion on a proper basis with any competent person who would go to Vienna and make the studies that he had. He predicted that all who did so would find his facts correct, and the facts once admitted, his own views were the logical deductions. He claimed, in brief, a certain normal relative size between the heart and lungs. In nearly all cases dead of phthisis, he found the proportion between these organs widened. Either the heart was preternaturally small, or the lungs were abnormally large, or both conditions coëxisted in the same individual. He reasoned that when the proportion between these two organs became too wide, the heart was incompetent to properly supply the breathing

*Die Ætiologie der Chronischen Lungenschwindsucht, Berlin, 1885.

apparatus with blood. If this did not show itself in childhood, it did at puberty, and was accompanied by palpitations, dyspnœa after very moderate exercise, loss of appetite, and, naturally, a disinclination for physical work. This caused a natural tendency to increase the trouble by promoting the avoidance of physical exertion, and compelling the growth of sedentary habits. Malnutrition of the lungs due to an inefficient heart, were the anatomical factors that generally predisposed people to phthisis. Lungs whose mobility becomes restricted, either by pleuritic adhesions, or by fixation of the chest walls due to calcification of the costal cartilages, have a diminished blood supply, and consequently lessened nutrition.

The observations of Koch,* and his deductions, almost completely obscured these determinations of Brehmer, and even yet constitute a barrier to their being generally known. The claims of Brehmer, however, were in time acknowledged by the very men who at first so strenuously opposed them. Some of these gentlemen pursued the studies he had invited them to make at Vienna, and with the result of becoming converted to his views, as he had predicted they would.† The facts as he stated them could not be denied. His deductions were logical and correct. So far as I am aware, no man to-day thoroughly qualified from personal experience to speak on the subject upholds a contrary view.

Curiously enough, Koch himself has been the means of strengthening Brehmer's theory. Of the former of a number of experiments on animals, in which he made intra-thoracic injections of tubercle bacilli, some lived despite this treatment, and upon being killed after many weeks, showed very circumscribed miliary tubercles at the seat of the former injections. The reasons for these exceptions were not satisfactorily inquired into, so that it cannot positively be claimed that all those that escaped general infection had a superior pulmonary nutrition. The exception, however, can only be explained on the supposition that there was too much resisting power to permit the spread of the injected colony of bacilli; in other words, there was no predisposition. Given a patient so predisposed, and barring all accidental interferences, and he will die by his lungs. Given the same patient under good circumstances, and in fair conditions, and tubercle bacilli will be impotent in their influence. Given the same patient again, but under disadvantageous circumstances, even in poor health, and the bacilli may be said to be potent for evil, but whether there be any of these organisms or not, the lungs will fail anyway unless the sufferer's conditions are rapidly bettered. On these grounds it seems fair to say that the tubercle bacillus is not the dread microbe it is represented to be.*

It has now become the fashion to ascribe all deaths in surgical cases accompanied by fever as due to germs or micro-organisms. The majority of believers in this doctrine have no definite basis for their convictions. Having been taught to so view the matter, they adopt the opinion of their teachers, and seek to impart them to others by precept and example. That extreme antisepticism would never have reached its present status if all men were their own judges, I have made it my business to prove. At the present day we smile, amused at the extremism of a few generations ago, when phlebotomy was so universal, and even now, advanced thought based on better facts is forcing the so-called antisepticist to leave his self-constructed pedestal, or be consigned to the position of his recent sanguineous predecessors. It is very common to hear all ailments ascribed to the activity of "disease germs." Let the surgeon of the day, the one in fashion I mean, operate upon a patient

*Appearing mainly in the Deutsche Medicinische Wochenschrift and Berliner Klinische Wochenschrift in the early eighties, besides some other journals and monographs. He even himself says that "un dennoch einige schwer oder gar nicht zu dentende Katsachen da bleiben, welche uns zwingen, vorläufig die Annahme einer Disposition bestehen zu lassen." He consequently confesses that he is *compelled* to admit the weighty indications of the necessity for predisposition in the development of tuberculosis.

†One of the most prominent of these converted opponents was Beneke, who, although he had mercilessly criticised Brehmer, and denounced his views as entirely too one-sided, after a sojourn of some time in Vienna, whither he had gone as Saul, says Brehmer, and returned as Paul, wrote a book entitled "Die anatomischen Grundlagen der Constitutions-Anomalien des Menschen." Herein he admits his former errors, and joins hands with Brehmer.

*Pütz, "On the Relation of Tuberculosis of man to Tuberculosis of Animals," etc., 1883, relates a number of experiences that demonstrate the necessity of predisposition. On page 30 he mentions how he injected 12 c.c. of tuberculous matter, expressed from still warm tuberculous human lung, into the abdominal wall and cavity of a ten months' calf. Ten weeks after the injection, the animal meanwhile not having had a single local or constitutional symptom, was killed and showed a connective tissue induration at the seat of injection. The peritoneal surfaces were perfectly normal in every way. Nowhere were there found any evidences of tubercles or tubercle bacilli, though they were zealously searched for. Four c.c. of the same fluid was injected directly into the substance of the right lung of a one-year-old foal on the same day. There was fever with increase i pulse beat and re-pirations for about four weeks. A few days later the foal was killed, and scar tissue and tubercles found at the seat of injection and a little beyond. Yet not a vestige of tubercle bacilli could be anywhere discovered, even after the most diligent search. These are two sample cases. Others might be cited in which similar injections were followed by more or less formation of tubercles and tubercle bacilli, but the bacilli were found in large quantity mingled with micrococci or other bacteria, thus negativing Koch's assertion that the true bacillus tubercle was not found with micrococci, or showing that the bacilli found were not those of tuberculosis. However this may be, the conclusion either way would be more or less damaging to the views of K., and supportive of those of Brehmer.

and the end be fatal, and the only conception his mind seems capable of is that it was a case of "too much germs." If the patient gets well, it is because the germs were excluded from the wound by protective dressing. When, however, a skeptical brother comes along with a successful case in spite of germs, and with no preventive dressing, the cry is, that God had helped the patient! It seems almost impossible for a man once wedded to this idea, to ever divorce himself from it to impartially consider the question. Judging from the prompt acceptance and spread of antisepticism, without consideration by those adopting it, the cause would seem to be a special mental microbe.

The patient himself does not receive the proportion of attention he deserves. A patient at hand sufficiently diseased or injured to excuse surgical interference, is operated upon as soon as is convenient for the surgeon, and when all antiseptic preparations are completed. It is the rule to ignore the preparation of the sufferer for the coming strain upon his vitality.

The questions arise: What is antisepsis? Why is it used? What is its value? When and how should it be employed?

Antisepsis may be stated to be, *The prevention of contact between open tissues and living disease germs.**

The object of this antisepsis is to prevent this contact, on the supposition that it generally results in a more or less dangerous constitutional disturbance of the patient, and is quite often followed by fatal results. This operators accomplish or seek to accomplish by continuously spraying or douching the wound and cleansing of the neighboring parts and their own hands and implements with antiseptic solutions of various kinds, and an antiseptically hermetic sealing of the wound till union is effected.

If now we take any wound with coaptated walls, we expect to get primary union under certain conditions. These consist essentially of

a. Absence of all foreign matter.
b. Perfect coaptation of the surfaces.
c. The maintenance of perfect coaptation.
d. A certain degree of local tonicity; and,
e. A certain degree of general tonicity.

The first condition is the one upon which the antisepticists base their *theory.* They claim that various microscopic bodies are capable of insinuating themselves through the wounded surface and into the tissues, there to multiply and be spread broadcast all over the body, to breed those symptoms which are invariably produced by their presence if in sufficient number. To obviate this, they have discovered many substances that will poison or intoxicate these little bodies so as to make them harmless, and this, they claim, without damaging the patient. Dolly,* in his recent work, gives an account of over fifty varieties of microbes supposed to produce as many different diseases. His list is not greater, he informs us, because he did not want his book to assume larger proportions, and not because there were no more to add.

If these little germs were the producers of certain diseases, these diseases should not exist in cases where perfect precautions had been taken to destroy them. The claim is that certain bacteria produce a fatal or almost fatal rise of temperature after surgical operations, and that such thermal elevations are never due to any other cause. Given, then, a large wound and perfect antisepticism, as regards spraying, douching, and subsequent dressing, with many layers of antiseptic gauze, and it is utterly impossible for the patient to get the symptoms supposed to be produced by the special pathogenic microbe. Should, however, such symptoms fully appear in defiance of perfect precautions, then the supposition that the disease is caused by microbes is demonstrated to be a fallacy.

A characteristic microbe has been found in diphtheritic membranes. Hence, microbists have concluded that this body is the cause of this disease. A certain solution of mercuric chloride was found to be sufficiently strong to destroy them. A woman in childbed had her vagina and cervix continually douched with this solution of ample germicidal strength, and in spite of this there formed in that vagina a typical diphtheritic membrane. This membrane was a perfect cast of the canal from which it came. Here is one negative experience with no chance for error, and it demonstrates conclusively that the characteristic microbe is not the causative element in the formation of this membrane or of this disease. In a question of this kind, one negative experience, if without error, is logically as effective a refutation of a theory as are thousands.†

*The reader is urgently requested to bear in mind the *exact* meaning conveyed by the definition.

*Technology of Bacteria Investigation, 1886.

†This conclusion has been objected to because it was alleged the bichloride solution would coagulate the albuminous constituents on the surface of the vaginal mucus and protect the remainder underneath from any further action of the fluid. The same individual accounted for the success of the hot douche employed by Dr. Varich, of Jersey City, and others, by its power of killing germs. When confronted with the two statements, he explained that the hot water's action extended deeper than that of the bichloride. Now

The well authenticated fact that some septic and other so-called infectious diseases diminish in proportion as higher altitudes are attained, and at the same time a proportionate decrease of germs is also observed, has led to the claim that the diminution in the frequency of the disease was due to the lesser amount of germs. It is, however, equally as rational, in fact more so in our present state of knowledge, to assume that one and the same cause lessens both the disease and the microbes. They do not bear to each other the relation of cause and effect, but are rather both the effects of a third etiological factor.

To enumerate the many failures of perfect antiseptic precautions in preventing so-called septic fever is not necessary. Very likely every man present has had personal experience of such failures. Many have been reported from all parts of the world where antiseptic surgery is practised, and that too by the most ardent disciples of Lister. In fact, Lister has himself reported such failures, and at the International Congress that met in London, he confessed that it was his conviction that patients under his care had been poisoned to death by the rigid application of his principles. When the impetus a new and striking idea receives is sufficient to cause the death of the ones committed to the care of those who support and apply these principles, it may be safely called an extremism—a dangerous extremism. It is this wholesale running away with men's minds that I would contend against this evening. Whoever has witnessed without bias an operation under rigid antisepticism, and has carefully observed the mental attitude of the principal surgeon and his assistant staff, could not help being impressed with the singleness of purpose and the narrowness of view of this same chief operator during the operation, although otherwise a man of superior mind. This warping of better minds is dangerous.

Having noted in a brief manner that perfect antisepticism frequently is ineffectual in preventing the conditions supposed to be produced by the germs that it is intended to cut off from entrance to the wound, it is proper to turn to that class of cases which make typical recoveries without any so-called antiseptic precautions. I will cite a few striking instances as examples.

Five puerperal cases of Dr. Josephine A. Dufré are instructive. The first, third and fifth died with high temperature, and all the accompanying symptoms of septic infection, although every possible precaution was taken against sepsis, such as baths, change of cloths, and the non-attendance of contagious or infectious diseases. The second and fourth recovered with a clear history, although no precautions whatever had been taken to avert sepsis, and the doctor was even in daily attendance on a case of erysipelas. These facts go without comment.

Dr. E. H. Bartley informs me of the case of a pregnant woman daily expecting the birth of an offspring, who was in constant attendance upon one of her children very sick with scarlatinal diphtheria. In the midst of her nursing of this child, she took to bed and was delivered by Dr. Bartley, who treated her and the scarlatinal child together without the mother developing a bad symptom, and this without any antiseptic prophylaxis. This case, too, goes without comment.

Another instance I would mention is one that occurred in the practice of Dr. W. J. Brandt. He was attending a case of malignant erysipelas, of whose malignancy there could have been no doubt, as the patient died. While handling and dressing the erysipelatous part, he was hastily summoned to a case of abortion, in which he delivered with the same hand that had been employed on the previous case; and although he had in his hurry forgotten to wash or even rinse his hands, the abortion patient recovered without a bad symptom. This case, also, goes without comment.

Dr. Chas. Jewett's case of diphtheritic vaginal cast at the Long Island College Hospital has already been alluded to, and does not require reiteration or comment.

Our President, Dr. Benj. F. Westbrook, who, during the first eight years of his practice, did a great deal of work as a practical pathologist and anatomist, and without taking anything like the present extraordinary precautions against infection, attended a large number of obstetric cases, and of all these does not recall a single instance of septic fever—so-called. Since dropping his anatomical and pathological work for the purpose of giving all his attention to the heart and organs of respiration, he attended some more confinements, and from among this number he does recall several with marked hyper-pyrexia. Comment is not required.

Dr. A. Warner Shepard, who for the last

---

the bichloride in a sol. of 1-1000 or 1-2000 will make no appreciable difference in the albuminous constituents of vaginal mucus. Its effect in the vagina as regards the secretion is like water, *i. e.*, it dilutes and washes out the mucus, leaving the membrane freely exposed and rough to the touch. So that it *is* proven by the above-mentioned case and other similar ones that a diphtheritic membrane forms without the agency of germs.

twenty years has *constantly* been making very many post-mortem examinations on all kinds of cases, and who *never* employed antiseptics in either his obstetrical or surgical practice, both of which have been very extensive, hardly recalls a failure of primary union or more than a slight reactionary fever, except perhaps when such results were epidemic and also occurred under antisepsis.

My former associate, Dr. H. T. Halleck, in a series of minor surgical operations, all without antisepsis, had uniformly successful results as regards the healing by primary union and the absence of fever.

In my own practice (hospital, dispensary, and private), in a period extending over four years and a half, every surgical case, with only four or five exceptions, was so treated as to carefully avoid anything that might be construed as antiseptic. Yet in all these cases, I have still to note my first failure to obtain primary union when it was attempted. The list comprises a number of injuries and operations, from a simple incised wound or amputated prepuce to an excision of the left upper jaw and part of the adjacent bones. I have purposely refrained from detailing any of my cases or tabulating the whole list, because these experiences are very common, and especially so among men who combine post-mortem work with operative surgery. It was the rule in my own cases to operate shortly after having made a post-mortem examination, or after the handling of anatomical material in various states of preservation. Soap and water was the only material employed to cleanse the hands, which, however, did not prevent the usual post-mortem aroma.*

I may here parenthetically remark that the cleansing of the hands from the odor from autopsies is more satisfactorily accomplished by constant rubbing and rinsing in a stream of running water alone than with the additional use of soap. This I suppose to be due to the adherence of the odor being due to its incorporation with the fat of the cadaver, and the difficulty of removing this when additional fat (soap) is added. The plain water seems to float the grease off the hand, and with it the odor. The cleansing is as complete as it can be when the hands feel rough whenever they are rubbed together.

In the service of Dr. Joel W. Hyde, at St. Mary's Female Hospital, it was the custom to give each obstetric patient one or more antiseptic vaginal injections per day after confinement. During this time it was the rule to have a higher and more lasting fever than could be called reactionary. It was peremptorily ordered that all injections should be discontinued, and from that time until the present, while no kind of vaginal injection has been practiced, it has been exceptional to meet fever in the maternity wards. This experience extends over too long a time, and embraces too many cases, to be considered a coincidence. Dr. Bartley also has made the same observation in his private practice—fever with injections, and no fever without injections.*

Lawson Tait, formerly one of the most pronounced advocates of antisepticism, had his (up to that time) wonderful successes triumphantly pointed to as demonstrating the immense advantage of antiseptic surgery. Now, however, after having wholly discarded all antiseptic practices, he exceeds his former successes with an unbroken list of one hundred and twelve unselected cases of ovariotomy and oöphorectomy without a single death. He simply observes cleanliness during the operation besides developing the resisting power of the patient before the strain and maintaining it in the most careful manner afterward until recovery ensues. This is accomplished through the nervous, muscular, and vascular systems and the nutritive apparatus. So important does he consider the condition of the nervous system that the personal acceptability of the nurse to the patient shall be as complete and pleasant as possible. I have elsewhere already insisted upon the necessity of having the nurse acceptable to the patient.† Whatever contributes to the ease, comfort, and pleasure of the patient at the expense of what is hard,

* Absorption must almost of necessity be as easy from a simple incised wound having, say, an extent of surface equal to one or two square inches, as one ten or twenty times as large. If germs cause fever, they should be practically as effective on a small surface as on a large one. They are capable of multiplying. The question is one of absorption and a struggle between cells and germs. Now whether the surface be large or small, the proportion of germs active in a given area remains the same. The trouble at first is purely local between the germs and cells. If the cells connot overcome the germs, the latter are supposed to overcome the former, and it is only after winning in this local battle that the dread microbes can enter the system to spread havoc. This is the platform of the microbist. It is not irrational. It is the intermediate and conciliatory view. This all being accepted, the question of great interest is, why should minor surgical cases and small wounds not give rise to septic trouble and refuse to heal promptly, as do a larger proportion of major cases? Germs do not explain it. The condition of the patient does. Major cases are more devitalizing, and diminish more the resisting power and leave less for local tonicity.

* I would in this connection call attention to a paper by Dr. Hiram Corson, of Pennsylvania, appearing in the *N. Y. Medica Journal* of May 15, 1886. Besides being written in a master manner, it contains the fifty years' experience of a venerable practitioner and writer, in the treatment of over three thousand cases of labor without antiseptics. He does not recall an instance of puerperal fever, and did not have a single death. The seductive manner in which the paper is written, and its insinuating tone, will hold the attention to the end of any one who begins its perusal.

† The Treatment of Scarlatina—Section II Archives of Pediatrics, Nov., 1885.

uncomfortable, and disagreeable, adds to the general tonicity, adds to the vitality, and increases the resisting power of the patient to an appreciable extent, and just in proportion as what may be called the operative period of the patient is pleasanter and healthier than the preceding period; just in the same proportion is that patient's chance of perfect recovery increased, provided that care has been taken in the proper prepara tion of the patient.

As has already been stated, very little if any attention is given to the adequate preparation of a subject for operation. Granting that such preparation is made and is ample, it is often counterbalanced by comparative neglect after the operation. Hospital cases generally, do not fare as well as those that are privately treated. The mortality in general hospitals is higher than in private practice for the same procedures. This is claimed to be largely if not altogether a question of infection, but it is not a question of infection. Note the difference in the general run of hospital and private cases. The great majority of the former are such as have poor and defective homes, and are lacking in means to maintain an existence in average health, in spite of hard and persevering labor, or else they have neither home nor means. Privation and suffering is the rule for a great many hospital cases. It is otherwise with those in private practice. The great preponderance of this class have sufficient means to pay for the attendance of the surgeon, the operation, the assistance of others, and for medicine, special diet, and experienced nursing. These people live better. They are better prepared to meet the strain. They receive the greatest attention from their visiting surgeon, who does not hurry with these patients, but hurriedly passes from bed to bed in the hospital wards, relying largely on the resident physician, upon whom the responsibility does not entirely belong, and where it is not assumed. Even resident physicians depend largely upon nurses and they upon one another. I speak now of general hospitals. In special hospitals some things are better than in private practice, while others are not as good. But it is more expensive to get into a special hospital, as a rule, than it is to be treated at home. Only a few if any charity cases are admitted, and even here the distinction is maintained between the patient who pays and the one who does not.

Another point illustrative of the defects in hospital treatment as compared with that in private practice is, that nearly all are fed alike. Take one hundred surgical cases in an hospital. Give each the same kind and quantity of food. More especially is this so in military hospitals on or near the field. One out of this hundred has a stomach that will extract everything available out of the food presented. Another will prove the antithesis of the one just mentioned, and gastro-intestinal irritability, lack of nutrition, loss of strength, and of resisting power will result. Reaction becomes impossible. General and local tonicity, which may have existed at the beginning, gives way to flaccidity, anæmia, hyper-pyrexia, pyogenesis, general disintegration, and death. This is not a question of infection. Bad food is the fundamental causative factor in bringing about such a result.

The old saying that "It never rains but it pours," is exemplified by this illustration, when we bear in mind that most general hospital fare, especially that given to no-pay patients, is not as good as that which even the poorer people provide for themselves. A young salesman or saleswoman from any of our stores, earning enough money to board in a house that is well furnished and provided with good table board, becomes ill or is injured and must be taken to the hospital, and as their slender income is at an end, they are classed as charity patients. Their environments have suddenly, and at the worst possible time, undergone a notable retrogressive change. Will any one refuse to admit the potency of this change in its effect on recovery from any illness, injury, or operation? Add to the poorer environment a diet decidedly inferior, both as regards nutritive value, quantity, and palatability, and we have at once a very depressing factor added to what the patient is already battling against in its tendency to pull down the whole organism. Yet this is a factor that is either not at all considered, or passed over as of no consequence.

(To be continued.)

Medical Societies.

PHILADELPHIA CLINICAL SOCIETY.

The Vice-President, Dr. Daniel Longaker, in the chair.

Injury—Abscesses—Syphilis—Amputation.

Dr. Henry Beates reported the following case: The patient is 29 years of age, by occupation a fresco-painter. He has been perfectly healthy until the present trouble was acquired. Eight years ago he fell from a

scaffolding, fracturing the right thigh and severely contusing the hip. Three years later, after exposure to wet and cold, he suffered from a severe right sciatica, accompanied by marked muscular atrophy, which lasted eleven weeks. The muscles soon acquired their natural size, and after a few months the slight resulting lameness entirely disappeared. About one year from this a swelling appeared in the affected limb just below the gluteo-femoral crease, which spontaneously opened and discharged pus, and two or three small fragments of bone. This was neglected for two years, when occlusion of sinus occurred, resulting from lodgment of an osseous fragment, followed by accumulation of pus, with subjective symptoms, The fragment was removed, with the result of complete healing of the part. He remained well until late in the spring of '85, when he contracted a specific chancre. The constitutional phenomena manifested themselves about six weeks later, in the usual form of angina, fever, mucous patches, and roseola. At the same time an excruciating pain, unaccompanied by redness, swelling, and heat, developed in the right tibial head. This was most severe, and for its relief necessitated large doses of opium. After one week the knee-joint became swollen; this rapidly increased, and involved the leg, the calf soon becoming tense. Free incision through the gastrocnemius evacuated about half a pint of pus, which is presumed to have burrowed way down behind the posterior tibial surface from the orifice in the ligamentum postium. Notwithstanding this free drainage various openings established themselves about the articulation, and it became very evident that the limb was doomed. The patient refused radical measures until spontaneous luxation occurred, and the profound hectic and paroxysms of exhaustion convinced him that death was near. For several weeks the temperature range was between 100° and 102°. There were pronounced chills with profuse sweatings, and the pulse-rate continuously above 120. A huge abscess that fluctuated on the right side of spine, about the junction of upper and middle thirds of thoracic vertebræ, and extending down behind the pelvic fascia into the gluteal region, existed on the opposite side. That this was one large cavity was proven by the fact that pressure upon either the gluteal or spinal prominence occasioned bulging at the other. In September, assisted by Drs. G. Davis, G. Faught, C. Dock, and Mr. Morris, I amputated the limb at the junction of the middle and lower third of femur. The operation was followed by profound shock, from which, after considerable difficulty, reaction was established. The after-treatment occupied several weeks, and embraced, in addition to the anti-syphilitic measures, evacuation of the enormous abscess. This completely healed, and the patient is now apparently well and stouter than ever before. Examining the specimen, we find that the internal and external vasti muscles have been separated from the femur by pus; that on the inner aspect extended along the femur quite a distance. At the time of operation it was thoroughly scraped, and gave no subsequent trouble. The knee-joint is seen to be completely restored. The semi-lunar fibro-cartilages are gone, and even the anterior and posterior crucials. The capsular and lateral ligaments are eroded and perforated in many places, while the transverse and coronary are not seen. Sawing through the femur, joint, and tibia, we find the patella bound down to the condyloid surface of the femur and the tibia greatly diseased. Its head is rarefied and crumbling; slight pressure breaks it down. The process involves the superior tibio-fibular articulation, which also is destroyed.

The medullary cavity of tibia is the seat of purulent deposits throughout its entire length, while externally at the middle of the crest is a ridge of granulation tissue.

A microscopical study of sections prepared by Dr. Henry Formad discloses every evidence of an intense inflammation. The Harveian systems are completely disintegrated in many areas, and in the place of lamellæ with lacunæ and canaliculi, are wide spaces which, in some places, are occupied by leucocytes and blood corpuscles. Complete absorption of Harveian systems is common, while in some areas where osseous structure can still be recognized, the osteoblasts are distended and the canaliculi correspondingly filled. Areas occupied by inflammatory exudate and product manifest a decided tendency toward fusiform connective tissue cell development, which is especially conspicuous about the arteries. These show a pronounced proliferation of connective tissue about their external coat and between the internal and muscular layers. Longitudinal section of the Harveian canals discloses them to be dilated and filled with cells, and where some anastomose there is a marked tendency to absorption of bone tissue.

Extra-Uterine Pregnancy—Rupture of Sac—Death.

The report of the following case, with specimen, was sent to Dr. Smith, of Millville, N. J.

"Mrs. ——, æt. 40, one daughter æt. 19, several miscarriages since, about three months pregnant, with no unusual symptoms, was taken with a sudden pain in the uterus, supposed to be uterine colic, to which she had been subject, vomiting a good deal. Had had considerable vomiting of pregnancy. I was called and gave a a hypodermic of morphia; administered bismuth and oxalate of cerium. There was nothing to arouse my suspicion of special mischief. She was lying on the lounge dressed, so I did not examine the abdomen externally. The next day carbolic acid and cardamom relieved the vomiting; bowels not acting, small doses of calomel, followed by enema, produced relief. Entire recovery followed quickly. Twelve days later I was called in haste, at noon. The patient had been sewing all morning, when suddenly she had a spasm of severe pain in the abdomen. She was carried to bed, where I found her almost in collapse; pulse scarcely perceptible, face blanched. Upon stimulation she rallied, and after a careful abdominal examination extra-uterine pregnancy was diagnosticated. She improved during the afternoon, rested quietly in the evening, and died suddenly at five o'clock the next morning.

Autopsy thirty-three hours after death. On opening the abdominal cavity we found everything afloat in blood, which being removed, we found the diagnosis verified to the letter. A three months' fœtus developed in left tube, sac ruptured, save the amnion, which is intact. Beyond this the uterus has several fibroid intra-mural tumors."

Dr. Daniel Longaker then reported a case of

Icterus Neonatorum,

in which death occurred on the ninth day.

"L., white, was born in my ward, in Philadelphia Lying-in-Charity, after a normal labor. Male sex, and weighed seven pounds at birth. The mother had some milk at the time of delivery, and the secretion soon became abundant. During the first four or five days the child nursed, but at the expiration of that time it did so very imperfectly, and a day or two after it was entirely unable to draw the milk from the over-distended glands. Icterus had, by this time, become general, the entire surface was of a deep yellow hue, as well as the conjunctivæ. The urine was scanty, dark-colored, staining the napkin. The child was constipated, but it had small stools, which retained during this time traces of the meconium. At this time, also, it was observed to have oscillation of the eyeballs with convergent squint. There was also occasional rigidity of the muscles of the back and of the extremities. The fontanelles were all depressed, and the cranial sutures could easily be seen.

The child being unable to nurse was fed upon peptonized milk; stimulants and small doses of calomel were administered. There no difficulty in swallowing. It slept but little.

The case was regarded, from the first, as of more serious nature than an ordinary case of jaundice in the new-born. Death on the ninth day.

Autopsy ten hours after death. Rigor mortis. The entire surface was of a deep yellow color. No evidence of peritonitis. Nothing abnormal in the fœtal vessels. The vicinity of the duodenal orifice of the common duct had no mark of bile. An attempt to inflate it was unsuccessful, but later, with some perseverance, I succeeded in passing a small bristle from the duodenum through the common into the hepatic duct. The gall bladder was apparently distended."

Mary Willits, M. D.,
1527 *Green St.* *Reporting Sec.*

NEW YORK NEUROLOGICAL SOCIETY.

Meeting of May 4, 1886.

C. L. Dana, M. D., President-elect, in the chair.

Address of the Retiring President.

The address of the retiring President, Dr. W. R. Birdsall, absent through sickness, was read by the Secretary, Dr. Geo. W. Jacoby. Dr. Birdsall reviewed the work of the society for the year, and expressed satisfaction at the number and quality of the scientific contributions and the interest which they had awakened, at the increased attendance on the meetings, and at the harmony which had prevailed in their counsels. He had not shared the fears of those who had believed that the organization of a section in neurology in the New York Academy of Medicine would have a detrimental effect upon the activities of this society. The year's work had shown that such fears were not well founded; that this city could support two societies in neurological research without the one detracting from the merits of the other. Both societies had thrived, and the one over which he had had the honor to preside had been able to receive only one-half the number of papers offered. Dr. Birdsall thanked the society for the honor which it had conferred upon him, and expressed regrets that unavoidable absence

deprived him of the pleasure of introducing the President-elect.

Inaugural Address.

Dr. C. L. Dana, the President-elect, recommended to the society that it consider the question of abolishing the custom of having either a retiring or a formal inaugural address, unless these be made the means of presenting some scientific question. The suggestion might also be made whether it would not be wise to limit the membership of the society, or else to establish some qualifications for membership. Dr. Dana said he would call the attention of the members to a large gap which existed in our knowledge of the etiology of nervous diseases, and to the need of closer examination into this branch of that specialty. At present, our knowledge of the etiology of nervous diseases (leaving out poisons) might almost be summed up in three words: heredity, syphilis, and rheumatism. Was it not possible that neurologists had neglected to apply the ideas with regard to micro-organisms and infection which were now dominating in pathology? It was true, however, that Leyden had found a micro-organism in cerebro-spinal meningitis, Resenbach the bacillus of tetanus, and Strumpell had urged the view that acute anterior polio-myelitis was an infectious disease, etc.; yet these points were not solidly established, and the relation of infectious poisons or parasites to nervous diseases deserved closer study. It had seemed to him that many cases of the chorea of Sydenham were really infectious in origin. He would also call attention to the possibility of a parasite being at the root of some of the neuro-degenerative disorders, such as ophthalmoplegia externa, bulbar paralysis, and progressive muscular atrophy. The necrobrotic process which took place in these disorders was often so steadily and frightfully progressive, so nearly malignant in its fatal course as to suggest some active agency behind it.

History of a Case of Primary Labio-glosso-pharyngeal Paralysis.

Dr. E. D. Fisher presented a patient whose history was as follows: Mrs. H., æt. 43, has always enjoyed good health up to July, 1885. At this time she lost her eldest son, who was accidentally drowned. She was much affected by the loss, and was constantly crying and calling for her son. The following September she first noticed some difficulty of speech and inability to move her tongue freely, with also some difficulty in swallowing. Dr. Fisher saw the patient for the first time in February. She then presented the following symptoms: Inability to protrude the tongue beyond the teeth, to form the lips so as to whistle or blow, the lower lip being down, and the saliva ran freely from her mouth. The lower part of her face was expressionless. No loss of power of the upper muscles of the face. The patient was unable to pronounce linguals or labials, and also, as the palate was partially paralyzed, was unable to pronounce the explosives: all her tones were decidedly nasal. Her food had to be pushed with her hand to the back of her mouth, when with difficulty it was smallowed. There was no tendency for liquids to return through the nose, but they would come out of the mouth. There was no loss of sensation or taste.

The faradic current was somewhat decreased in reaction, but there was no reaction of degeneration to the galvanic current.

These symptoms have all increased since first seeing the patient, and she has lost about twenty pounds in weight. There are no signs of paralysis of the upper extremities; the disease is located entirely in the bulbar nuclei.

The interest of the case lies in the fact that the cause can be clearly traced to the excessive grief at her loss.

Dr. Fisher suggested that in the discussion of the case by the society, recognizing the lesion as seated in the fourth ventricle, involving the hypoglossal, facial, vagus, and glosso-pharyngeal, the question of the situation of the facial muscles be taken up. Clarke has mentioned that the facial has a lower nucleus for the orbicularis oris, and Gowen thinks that fibres for this muscle are given off from the hypoglossal nucleus. Either of these theories would explain the escape of the upper muscles of the face, as is usual in this disease.

DISCUSSION ON DR. FISHER'S PAPER.

The President said there were several obscure points for discussion which Dr. Fisher's case had suggested, among others the question of the etiology of labio-glosso-laryngeal paralysis, some features in its symptomatology and its treatment. Regarding the etiology, it was once claimed, he believed that the disease was always of specific origin. He had had three cases under observation the past two years, and of those only one gave a pretty clear specific history; in the other two no such influence could be detected at all. In the one, although the patient gave some some evidence of having had specific disease, yet it was simply assumption that this was the cause of the bulbar affection. In his opinion we could only

place specific disease among the predisposing causes.

Dr. Putnam Jacobi asked whether the patient had heart disease.

Dr. Fisher replied that the heart had been examined, and no evidence of cardiac disease could be discovered.

Dr. B. Sachs thought the case was one of great interest to all. Bulbar paralysis, he thought, was more common in Europe than in this country; there was scarcely a clinic at which one or more cases did not present themselves during the year. He had seen a number at the clinic for nerve diseases at Strasbourg, under Prof. Kussmaul. The etiological factor which Dr. Fisher had mentioned, particularly in his own case, deserved consideration. It was further interesting, from the fact that the central lesion in this disease and in diabetes was near the same region, and he had known of a number of cases of diabetes in which the etiological factor was intense emotion.

Dr. Sachs thought it was difficult to explain why an affection like that from which Dr. Fisher's patient was suffering, in which the pathology was similar to that of progressive muscular atrophy and polio-myelitis anterior, consisting of an affection of the nerve nuclei, there was not the reaction of degeneration in the muscles supplied by the affected nerve nuclei. But it was possible the reaction of degeneration would appear later.

Dr. Putnam-Jacobi thought the suggestion made by Dr. Sachs, as to the analogy between bulbar paralysis and diabetes as far as their possible origin in emotional influences was concerned, was worthy of consideration; and the question had arisen in her mind whether such emotional influence may not have first influenced the cardiac center in the medulla oblongata and secondarily contiguous centres. Dr. Jacobi spoke of certain anatomical considerations in connection with bulbar paralysis, and referred to several cases reported by Eisenlohr. It seemed to her that exemption of the upper branches of the facial nerve in typical bulbar paralysis was an extraordinary circumstance, and one which she would be glad to have explained. It seemed remarkable that in Dr. Fisher's case the symptoms should have remained so limited for so long a time.

The president had examined the urine for sugar in two cases of bulbar paralysis, but with negative results. With regard to the affection of taste, it was well known that that sense was not usually involved in bulbar paralysis. He had thought that the glosso-pharyngeal nerve at its nucleus was purely a sensory nerve, and that it received its motor fibres from the spinal accessory; that it supplied taste to the posterior, and perhaps to the anterior part of the tongue. The question as to whether it supplied general sensation to the fauces or posterior part of the tongue it seemed to him was involved in considerable obscurity. The cases which he had seen had given no positive evidence that the glosso-pharyngeal nucleus was involved, except in one in which there was disturbance of the sense of taste, and there had been two other cases reported in which this sense was involved. With regard to the seventh nerve, and involvement of its nuclei, he thought that in some cases the branches of that nerve were involved. In one of his cases the upper portion of the face was not wrinkled, the eyelids could scarcely be approximated, showing that the facial nuclei were becoming involved. Regarding the reaction of degeneration, it was never present except in the later stages. There might be partial reaction of degeneration at an earlier date. The explanation which he had given was that the trophic centres of the nerve were involved, causing atrophy, to which the paralysis was due.

As to treatment, he thought he should adopt a radically different form from what he had hitherto employed. It seemed to him that the cases improved for awhile under electrical treatment, and then such treatment seemed to make them worse. He would give the affected muscles complete rest if possible, and confine the electrical treatment to the stable galvanic current.

Dr. Sachs remarked that the phenomena of the reaction of degeneration might be present at first only to a limited extent, developing more completely as the case progressed.

Fracture of the Humerus; Paralysis of Sensation and Motion in the Forearm.

Dr. W. M. Leszinsky presented a man, aged 33 years, whom he first saw April 13th, when he gave the following history: Ten weeks before, he fell and fractured the left humerus at about the middle third, the bone, he stated, being completely divided without producing a perceptible injury of the soft parts. After the injury he found the fingers numb, there was difficulty in moving the hand, and the wrist had dropped. He received surgical treatment. When Dr. Leszynsky saw the patient his left upper extremity hung loosely by his side. All voluntary motion was abolished below the seat of the fracture. The shoulder muscles were not

affected. There was marked wrist-drop, and the arm was kept in the position of pronation. The elbow-joint was anchylosed in extension. There was but slight flexion, but a greater amount of supination obtained upon passive motion. There was decided swelling over the external condyle, and a large amount of callus over the seat of fracture, which had become firmly united. There was some atrophy of the intrinsic muscles of the hand, and probably of the muscles of the forearm. The skin was cold, blue, and mottled, and the hair and nails seemed to have grown less than on the other extremity. There was complete anæsthesia below a line encircling the limb three inches above the olecranon, tactile, temperature, pain and muscular sense being abolished.

Dr. Leszinsky then gave the result of the electrical examination when he first saw the patient and during the progress of the treatment, which showed that the condition of the limb was improving. He was of opinion that the nerves were injured at the time of the fracture, and not by the development of callus. The case showed the importance of an electrical examination in making a prognosis.

Dr. M. A. Starr thought that in Dr. Leszinsky's case, as in several which had come under his observation, an electrical examination at different periods was the best basis for a prognosis, and he should use the milliampere for exactitude. He had seen several similar cases in which the trophic changes were more marked than in the one related by Dr. Leszinsky.

THE CLINICAL SOCIETY OF MARYLAND.

Stated meeting held May 21, 1886.

Under the head of reading papers, Dr. George H. Rohé read a paper on

The Present State of the Doctrine of Parasiticism in Dermatology.

He reviewed the clinical and experimental evidence on the question, and concluded that the following skin diseases are demonstrably of parasitic origin: Favus, ringworm, chloasma, erysipelas, leprosy, and glanders. Other diseases that are sometimes considered as due to parasites, but in which the etiological relations of parasitic fungi or bacteria must be regarded as unproven, are boils, carbuncles, impetigo contagiosa, rhinoscleroma, pityriasis capitis, alopecia areata, psoriasis, lichen ruber, mal de los pintos, mycetoma, lupus and verrugas. Dr. Rohé thinks that although in the latter the proof is not complete, an affirmative demonstration is probable.

Dr. I. E. Atkinson wishes to disclaim any credit for the work upon the bacillus of leprosy referred to by Dr. Rohé. The work was the result of Dr. Berman's labors, and Dr. Atkinson simply demonstrated the specimens *for* Dr. Berman, who was unable to attend the meeting of the American Dermatological Association held at Newport. He was very much interested in Dr. Rohé's paper. He considers mycosis fungoid as beyond a doubt proved to be the result of the presence of a streptococcus. As to lupus the evidence varies; some observers claim to find the bacilli in small numbers, while others fail to find them at all. Don't think the evidence sufficient to justify us in classing it as a disease due to the presence of the tubercle bacillus. He referred to a certain wart formation recently described and grouped with the infectious granulomata under the name of verucca necrogenica, as being claimed to result from the local deposition of the tubercle bacilli. They occur usually at the point of wounds received while dissecting the bodies of patients dead of tuberculosis. He thinks it singularly at variance the one with the other, that if the localized deposit of tubercle bacilli should in one case produce lupus, it should in another instance give rise to a wart. As to the late work of Lustgarten on syphilitic new-formations, while he don't think it proven, yet he thinks the probabilities are in favor of its correctness. At all events, it presents many interesting propositions.

Dr. G. M. Sternberg said as to the local expression of tuberculosis, we commonly see tuberculous joint troubles in children, from which they make complete recovery. Cold abscesses he considers another example. Thinks the etiological value of micrococci in pus proven.

Dr. E. G. Waters read a paper entitled

At what Point in the Intestinal Canal do its Contents become Feculent?

DISCUSSION.

Dr. J. H. Branham don't think a Peyer's patch a secreting body, but rather an absorbing gland, and takes it to be a member of the lymphatic system.

Dr. N. G. Keirle thinks it difficult to say at an autopsy at what point in the canal the contents become feces, either by their odor or by their appearance.

Tuberculosis of the Retro-peritoneal Glands.

Dr. Keirle exhibited a specimen that he finally decided to be a tuberculosis of the

mesenteric glands. His opinion had wavered between a syphilitic adenitis and a sarcomatous process and a tuberculosis.

Dr. I. E. Atkinson, referring to the enormous glandular enlargements seen in primary syphilis in negroes, said that he took it to be rather a peri-adenitis than a proliferation of the gland elements themselves.

Dr. J. H. Branham asked if in scrofulous negroes suffering from syphilis, the tubercle bacilli were always found in the enlarged and caseous lymphatic glands.

Dr. A. C. Abbott replied that while it was generally admitted that the glandular enlargements with the caseations seen in scrofulous subjects whre the result of a tubercular process, yet it could not be said that microscopic examination always revealed the tubercle bacilli. The reason for this rests in the fact that they are here most probably in the spore stage, and as we have no staining re-agents that will satisfactorily demonstrate spores, we must resort to cultivation and inoculation experiments for their positive demonstration.

Death following Fracture of the Cranium.

Dr. N. G. Keirle related a case of a man who, after having fallen upon the back of his head, went about for eight days, when he died. At times he was more or less irrational. Autopsy revealed fracture of the orbital plate on the right side, and another fracture in the occipito-temporal region on the left side. These fractures were not continuous with one another.

Dr. L. McLane Tiffany said the fracture of the orbital plate was probably the result of counter-stroke. He cited the case of President Lincoln, who was shot in the back of the head on the left side, and sustained a counter-stroke fracture of the orbital plate on the right side. He demonstrated the physical principles involved in fracture by counter-stroke. He said that fracture of the orbital plate is most often the result of counter-stroke.

Dr. W. D. Booker related the case of a colored boy who had been kicked in the face by a horse. There was fracture of the frontal bone. A bit of the outer table was driven into the frontal fossa. On the following day a bit of bone was removed that looked like orbital plate, and a week later another portion came away. The left eye was enormously bulged out, and there was blood behind the conjunctiva. The eye was removed, the wound healed, and the boy is now doing weil.

CHICAGO MEDICAL SOCIETY.

Stated meeting, June 7, 1886, the president, E. J. Doering, M. D., in the chair.

Dr. A. Reeves Jackson read a paper entitled

The Intra-Uterine Stem in the Treatment of Flexions,

exhibiting the stems used.

The essayist began treating uterine flexions with the stem pessary in 1870. Prior to that time the only methods he had employed were gradual dilatation and incisions. The results were so unsatisfactory that he sought for a safer and more successful method. Having received the impression that the use of the stem pessary was more hazardous than either the dilating or cutting plans, he commenced its employment with misgiving, and did not rely wholly upon it, but preceded it with either gradual stretching or slight incisions. In two cases this mixed method was followed by pelvic abscess, a sequence which he had never observed when the stem alone had been used. All cases of uterine flexion are not accompanied by dysmenorrhœa or sterility, yet when there exists a relationship between these symptoms and an existing flexion, the latter must be looked upon as a mischievous factor, and one that should be removed. He had never treated any case of flexion in which dysmenorrhœa was not present, although coexistent barrenness has been frequently an additional incentive to the patient to undergo efforts at cure.

He preferred Chambers's bifurcated vulcanite instrument, although the divergence of the branches *below* the internal os uteri was a radical defect in the instrument, as ordinarily used. Frequently the branches should be closed, so that the stem might be practically single in that portion which traverses the cervix. His method is as follows: A flexion and its direction being diagnosticated, a flexible bougie is passed through the bent portion of the canal and quite to the fundus. The depth of the canal being carefully noted, a pliable stem, consisting of the distal portion of the same, or a similar bougie one-third of an inch shorter than the ascertained depth of the canal, is selected for introduction. A flange or bulb is formed upon the outer end of the stem by rolling upon it a section of rubber tubing. The woman being placed on the back in Simon's position and the os uteri exposed with a speculum, the stem either grasped with a dressing forceps or mounted upon the end of a piece of pointed wire, is passed entirely into the uterus. A large tampon of cotton moistened with slightly alumized glycerine

is pressed against the bulb of the stem, and allowed to remain one or two days. The tampon is removed and replaced at suitable intervals until the tendency of the stem to leave its position disappears. After this yielding stem has remained from one to three weeks, according to the degree of tolerance manifested by the uterus, it is removed and a thicker one put in its place. This likewise is permitted to remain a week or two, and is then replaced by a Chambers stem. While not very much, or, indeed, any change of shape is to be expected in consequence of the use of the flexible stem, yet, in several instances, a very considerable alteration took place within a few weeks, or even a few days, and in a few cases it was found unnecessary to resort to a rigid instrument at all. Usually, however, it had been necessary to use an inflexible instrument for from three months to a year—not continuously, but for periods of three or four months, with an interval of a week or two, during which the stem was removed in order to test the degree and permanence of the improvement. The feature of this treatment which is essential to its safety and success is its slow and gradual conduct, and the non-observance of this necessity has been the cause of dangerous results and failures to cure.

The drawbacks attending this method of treatment were:

1. Difficulty in retaining the instrument in position.
2. Pain.
3. Hemorrhage.
4. Pelvic inflammation—all except the first being common to all other methods treatment.

A table comprising the details of sixty-four cases treated by the intra-uterine stem alone was given, showing the ages and social conditions of the patients, the direction of the flexion, and the result of the treatment. Of the entire number 42 occurred in married and 22 in single women. Of the former 8 had borne children; the other 34 were sterile. Of the latter 8 subsequently bore children. A cure of the flexion followed in 40; of the remaining 24 four were improved and relieved of dysmenorrhœa. In 20 the result was unknown. The ages of the patients ranged from 19 to 39 years. The uterus was anteflexed in 50 and retroflexed in 14.

In conclusion the author said: "I believe the principle of the intra-uterine stem in the treatment of flexions to be correct; and it need not be dangerous—at least, no more dangerous than any other effective method. I further believe that by its use more cases of uterine flexion can be cured than by any other means at present in vogue. The conditions of both safety and success are watchfulness, patience, and slow progress."

Periscope.

Illustrations of Exceptional Symptoms and Examples of Rare Forms of Disease.

Mr. Jonathan Hutchinson reports these cases in the *Brit. Med. Jour.*, June 12:

Brachioplegia after Injury to the Head, with Fracture of Skull.

In the case of a little boy, whom I saw at the Poplar Hospital, and who was a patient of Mr. Corner's, the symptom of brachioplegia was of much interest. He was an intelligent little fellow, 7 years old. Riding behind a carriage, his head had become engaged in the spokes of the wheel, and much battered. When taken into the hospital, he was quite sensible. There was bleeding from his right ear, and considerable bruising of the scalp, especially on the right side, where there seemed to be some irregularity of the bone. He complained that he could not use his arms well, especially the right. During the next few days, large ecchymoses appeared on the conjunctiva of each eyeball, and the weakness of the arms increased. The accident occurred on October 16th. A fortnight after it, Mr. Archibald Andrews, the house-surgeon in charge, in writing to ask me to come and see the patient, stated that both arms were quite helpless, lying in a semi-flexed condition. The action of the biceps, he added, was perfect. It was more than three weeks after the accident, and a week after Mr. Andrews' note, when I saw the boy. He had been carefully kept in bed the whole time, and not allowed to try to stand. There had never been any retention or incontinence of urine, and it was recorded that his pupils had always acted well. It was believed that he had perfect use of his lower extremities from the first; but, it is to be ob-

served, he had never been allowed to try to stand. There had not been, from first to last, any mental symptoms whatever. At the time of my visit, he was intelligent and clear in his answers. His left arm had, when I saw him, considerably recovered. He could move it in all directions, and could grasp with the fingers, though not with natural power. The fingers of the right hand he could only move very feebly, and he could not grasp with them at all. By means of the biceps, he could bend the arm at the elbow, but, once bent, he had not the slightest power of extending it again. He appeared to have scarcely any power in any muscle excepting the biceps, and perhaps the brachialis anticus. We made him stand up in bed; he did not manage his legs well, but it was difficult to say whether this was more than might be expected after three weeks' absolute rest. When lying on his back in bed, he could kick freely. His pupils acted well, and no irregularity could be detected in the spines of his cervical vertebræ.

I came to the conclusion that the paralysis must be cerebral. There did not appear to be any defect of sensation in either of the arms, nor had had any disturbance of nutrition resulted. Muscular weakness and wasting was the one symptom, and this was unaccompanied by any indications of injury to the spinal cord. There was an irregularity down the right side of the skull, just over the ear, which clearly denoted fracture. It is very remarkable that there should have been no head-symptoms in the first instance, especially as both arms were involved. It must not be assumed as certain that the lower extremities had wholly escaped, since it is difficult, in so young a child, to estimate degrees of power without setting him to walk. It is quite certain that there was not, even at the first, any defect of the sphincters.

I heard, two or three weeks later, that the boy was up, and could walk well, and was regaining the use of his arms.

Simulation by Muscular Action of Dupuytren's Contraction of Palmar Fascia.

I saw, in the morning of July 11th, a curious example, in its early stage, of a tendency to contraction of the ring and little fingers into the palm; the contraction being due, not to bands of fascia, but clearly to the small muscles. The patient was a gentleman (Dr. S.), of a somewhat gouty family, but who had never himself had gout. His age was 62; and, excepting the trouble named, he was in good health. In the afternoon of the same day, it was my good fortune to see, in consultation with Mr. Freeman, of Onslow Gardens, a lady in whom the same condition had become much further developed. She was between 60 and 70 years of age, like Dr. S., of gouty family, but, like him, having never herself suffered a definite attack. She had been long liable to indigestion, eczema, and chronic glaucoma. When I first saw her hands (Miss A. T.), I thought that she was the subject of rheumatic gout, with great nodosities; but, on examination of the hand, I found that these appearances were simply due to partial dislocation of the joints, especially those of the knuckles. All the fingers were bent down into the palm, and carried over to the ulnar side. That there was no material contraction of fascia, was proved by the fact that they could be pressed back almost into the straight position. The hands were extremely emaciated, and the right hand was affected to a far greater degree than the left. Miss A. T. was crippled in her lower limbs by rheumatic gout, and always walked with a stick. I had no opportunity of examining as to their precise condition. She told me that the deflection of her fingers had commenced with her little and ring digits, and subsequently involved the others.

I will now return to Dr. S.'s case. He is a very healthy-looking man, and has lived temperately, always, however, drinking a little beer. One of his sisters is, he says, much crippled by rheumatic gout, and has had true gout. He himself has never had any arthritic affection; but, some years ago, I cured one of his sons of an eczema, which had long been chronic. On cursory inspection, there is nothing whatever to be noticed amiss with Dr. S.'s hands. He can, by effort, straighten his fingers perfectly, but there is a very decided tendency in the right hand, especially for the ring and little fingers, to be bent down into the palm. It is about a year since he first noticed this. At first, it was chiefly observable in the morning, after sleep, when the ring-finger would be so much contracted that he was obliged to use the other hand to straighten it. There is, perhaps, a very slight contraction of the palmar fascia; but that this is not the chief cause of the deformity, is proved by the fact that he can place the palm of his hand upon the table, and, by bearing weight on it, almost completely straighten the fingers. His chief inconvenience is in using his tooth-brush, and in carving; in these acts, the deflection is sometimes painful, otherwise it has not caused him discomfort.

It would take me too far to attempt to discuss here the precise shares taken by the different muscles in the production of these deflections of the digits. The reader will find much information on the subject in Dr. Vivian Poore's edition of Duchenne's works, published by the New Sydenham Society, and in the writings of Charcot and others on paralysis. My object in recording these cases here is to draw attention to the fact that the displacement began in the ulnar digits, and closely simulated, on the one hand, Dupuytren's disease, and, on the other, the common distortions of rheumatic gout. It is important to note that, in the latter malady, we not unfrequently meet with distortions which are of muscular rather than of joint origin. It is sometimes, indeed, difficult to say whether the conditions are due to arthritis or paralysis. I saw recently, in consultation with Dr. Hughlings Jackson, a case of this kind which was very puzzling. In these, the employment of galvanism for diagnosis is of much importance.

CONTRACTION OF THE LITTLE FINGERS IN A YOUNG LADY, WITH REPEATED ATTACKS OF SCLEROTITIS: INHERITANCE OF GOUT.

Mary P., aged 26, a governess, is of fair complexion. Her history of rheumatism is that, six years ago, she had an attack of rheumatism in her left knee, and for three months was carried about, not being allowed to walk. She had a little pain, but not much, in the other knee. There had been no injury or sprain. She quite recovered, and can now walk easily. She has never had rheumatism in her wrists, elbows, ankles, shoulders, etc. Her two little fingers are both contracted at the first phalangeal joint, the bones being at right angles. The last phalanx is not contracted, and can be straightened easily. It is doubtful whether the contraction is due to fascia, or to muscle.

In the right eye, she had several attacks of "rheumatism." The last has been the most severe attack. It began on November 2d, and she came to me on the 24th. There was then no evidence of iritis. She had at first much pain.

Her parents are both living. Her father has had a single bad attack of gout, in the great toe, about two years ago. Two paternal uncles have also had gout, and her paternal grandfather. One of her sisters has had rheumatism in one knee. She is very susceptible to the influence of east wind, as her hands become painful. She is myopic—16, possibly astigmatic. The vision of the right eye is not so good as the left. The patient is the fifth child; nine are living; none have had rheumatic fever. Her mother has not had rheumatism, but one of her sisters has "rheumatic gout." Her parents were first cousins.

The above notes are copied from some made many years ago.

The Treatment of Chronic Gastritis.

The treatment was thus laid down by Dr. Francis Delafield before the Association of American Physicians in Washington:

I. CLIMATE AND MODE OF LIFE.

These I believe to offer the most certain means of curing chronic gastritis. It is unnecessary to lay down rules as to the sort of climate, that can be regulated by the tastes of the patient. The two points of importance are: First, the locality selected must be one where the patient can lead an out-of-door life. Second, the patient must live in this climate either for several years, or for a considerable part of each year.

Excellent as this method of treatment is, it is evident that it can be carried out only by a limited number of persons.

II. THE DIET.

The regulation of the diet is a matter which demands consideration in every case of chronic gastritis. In trying to ascertain the best way of feeding these patients, I have found only one satisfactory method, and that is to feed them experimentally with different articles of food, and then after an interval of several hours wash out the stomach, and see how thoroughly these articles of food have been digested and removed from the stomach. After pursuing this course for a number of years, I have arrived at the following conclusions:

It is necessary that the patient should be well fed; a starvation diet never answers.

The stomach does not require any rest from the performance of stomach digestion; on the contrary, it is all the better for being called on to perform its natural functions.

The patient's own ideas as to what food agrees with them are usually erroneous. They are apt either to starve themselves or to select the least nutritious articles of food.

The use of artificially digested foods, or of substances such as pepsine to assist stomach digestion, is unnecessary.

The starches, oatmeal, corn meal, bread, the cereals, the health foods, are as a rule bad. Portions of them remain undigested in the stomach for many hours.

Milk in adults is an uncertain article. It

answers very well for some persons, not at all for others.

Meat is usually readily and well digested, but there are occasional exceptions to this rule.

Vegetables and fruits can be eaten, but the particular varieties must be selected experimentally for each patient.

I do not believe that any case of chronic gastritis is to be cured by diet alone. Even the exclusive milk diet, while it often relieves symptoms, is as a rule only temporary in its effect, so that the patient simply loses a certain amount of time by employing this instead of more efficacious plans of treatment.

III. The Administration of Drugs.

The advantageous use of drugs belongs to the earlier stages of chronic gastritis. At that time they often palliate symptoms and sometimes even seem to cure the inflammation. In the latter stages of the disease their use becomes more and more unavailing. The reliable drugs for this purpose are not numerous; the preparations of soda, potash, and bismuth, the mineral acids, glycerine, sometimes carbolic acid, sometimes iodoform, sometimes the bitter infusions. If none of these answer, it is hardly worth while to look any further. If we can combine with the administration of drugs, the regulation of the diet and of the mode of life of the patient, then of course our chances of success are much greater.

IV. The Use of Local Applications Made Directly to the Mucous Membrane of the Stomach.

This I regard as the most efficacious plan of treatment for those patients who are not able to leave home and seek a proper climate, but ask to be relieved without interruption to their ordinary pursuits. The local applications are readily made by the introduction of a soft rubber tube through the œsophagus into the stomach.

Liquid applications are the best. They should be made in such quantities as to come thoroughly into contact with the entire surface of the mucous membrane, although the pyloric end of the stomach is the region where the inflammation is principally situated. They should be made at a time long enough after eating for the stomach to be as nearly empty as possible.

For many cases warm water alone in considerable quantities is the only local application needed. In some, however, there is an advantage in medicating the water, and for this purpose I employ a variety of substances.

The alkalies, the mineral acids, bismuth, carbolic acid, the salicylates, iodoform, belladonna, ipecac, gelseminum, may each one be employed according to the particular case.

For the first week it is often necessary to put the patient on a milk diet, and this can be done even with those patients who under ordinary circumstances cannot take milk at all.

Then, after a time, to the milk we add one solid meal composed of meat alone.* Next, this single meal is increased by the gradual addition of fruits, vegetables, and bread. Then comes the giving of two solid meals a day, instead of one, then three solid meals, and now we get rid of the milk in part or altogether.

For the first week of this treatment it is wise not to expect any special improvement. Indeed, even a longer time than this may try the perseverance of the physician and the confidence of the patient.

Sooner or later, however, the expected improvement begins: the nausea and vomiting cease; the constipation or diarrhœa is improved; the flatulence is no longer troublesome; the headache becomes less frequent; and of more real value than these, the improvement in the general condition of the patient becomes evident. The color, the weight, the appetite, the sleep, the spirits of the patient, all show a change for the better. Of all the symptoms, the pain is the one which is apt to persist the longest.

For two or three months, the patient has to be kept under observation, and the applications to the stomach made by the physician. After this, the patient is dismissed, but continues the treatment himself, first every other day, then twice a week, then once a week for several months. The regular relapses of the disease are managed in the same way, but are much more quickly relieved.

An Impromptu Pump for Stomach Irrigation.

Dr. Sara E. Post, of New York, sends the following to the *Med. Record*, July 24th: Having recently a case requiring a stomach irrigation, I tried the funnel with the tube arranged as a siphon, in the manner usually recommended. The end of the tube with the funnel was elevated when pouring the water in, and depressed to induce its escape. The conditions were as perfect as possible, the portion of the tube outside of the body being

longer than that lying within. When the tube was first depressed the water ran out freely, but it was found that, as a rule, the stomach was not completely evacuated by means of it. After the flow had ceased, manipulation of the epigastrium would cause it to recommence. Apparently the tube, either by not being introduced far enough, or by being introduced at too great length, and curling upon itself, would fail to reach the most dependent part; and as it is difficult to calculate the depth of the dilated stomach, this objection could not be overcome. As a weak solution of the bicarbonate of soda was used for the injection, the washing would be followed by several watery evacuations, apparently due to the cathartic action of the retained salt. Also, the water removed by the siphon would be almost clear, while from the history of the case it was expected that mucus would be withdrawn.

Some kind of a force-pump seemed necessary to accomplish the desired purpose, and having a stop-cock with two outlets, a rubber piston syringe, a stomach-tube, and some additional tubing, a suitable apparatus was readily arranged. The three arms of the limb containing the stop-cock were provided with tubing, the inlet was connected with the syringe, one of the outlets attached to the stomach-tube by a short intervening glass, and the other connected with the weight from the receiving tube of a Davidson's syringe, and sunk in the receptacle containing the fluid to be injected. It will readily be seen that by manipulating the stop-cock water could be withdrawn from the receptacle and injected into the stomach, or withdrawn from the stomach and injected into the receptacle. Compared with the siphon this method was most successful. The water withdrawn during the first washings was gray, from its admixture with mucus. The washings were no longer followed by diarrhœa, and relief of the symptoms was early obtained. After six washings mucus is no longer returned in the water, a localized tenderness of several years' standing has disappeared, discomfort so great as to interfere with sleep and to make the patient dread food has been lost, and digestion has apparently been re-established. The patient eats three meals per day, and is commencing to have a healthy desire for food. It might be added that the patient had previously been under the care of good physicians, and presumbly had obtained all of the benefit which medication could give.

The washings are done three times a week, the patient taking no solids for six hours previously. Food could, however, be withdrawn by means of this apparatus, if the bore of the syringe and of the limb containing the stop-cock were sufficiently large. One quart of fluid is first injected and then withdrawn, the injection being repeated two or three times at each sitting. The introduction of the stomach-tube occupies but a few seconds. It seems better to force it down quickly, without much attention to efforts at regurgitation, as, when in position, the patient is comfortable, and breathes and talks with complete ease.

Previous spraying of the fauces with a four per cent. solution of cocaine facilitates the introduction of the tube.

This apparatus is, of course, not new. Its principle is exactly that of the ordinary stomach-pump. It is presented simply because while answering the same purpose it can be more cheaply gotten up.

Traumatic Tetanus Treated by Rest.

Dr. De Renzi states in the *Revista Clinica*, that by treating patients with traumatic tetanus by means of perfect rest he has been able to restore four out of five to health; whereas when treated in other ways these patients usually die in two or three days. He places the case in a special room where absolute silence reigns. Even in the passages leading to it and in the neighboring wards, care is taken to lay down carpets so that no sound shall penetrate the tetanus ward. The door to the latter is of course well oiled, so as to open and shut noiselessly, and the patient's ears are stuffed with cotton-wool, he himself being strictly enjoined not to make the slightest noise. He must, of course, be fed. This has generally been considered impossible, the teeth being clenched and the spasmodic contraction being increased by attempts to masticate. The obstacle may, however, be easily overcome by parting the jaws and introducing liquid food through a curved sound; swallowing is accomplished without difficulty. This method of treating traumatic tetanus has been tried with success by several Italian practitioners—Drs. Pisani, Maragliano, Ria, etc. The only disadvantage is that the affection is sometimes prolonged for two months. It seems to increase in duration as it diminishes in force.

—Two female medical students at Paris, the one French and the other American, had a dispute over the relative merits of French and American female physicians. This led to a duel with swords. The American received a slight flesh wound, when both were satisfied.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Dr. Dudley S. Reynolds, of Louisville, has returned to the journalistic field with a monthly called *Progress*. He has a good table of contents, and we hope will meet with gratifying success. The price is $2.00 a year.

—— The *Annals of Hygiene* has been resumed by Dr. Joseph F. Edwards, and the number for July gives promise of excellent and abundant material during the coming year. The price is $2.00 a year, and subscriptions may be sent to 224 South 16th street, Philadelphia.

——The causes and prevention of zymotic diseases are discussed in a pamphlet before us by Dr. R. French Stone, of Indianapolis.

——We have received the "Initial Prospectus of the Pittsburgh and Western Pennsylvania Female Hospital." We are well pleased with its objects as set forth; but are not pleased to note that not a single woman physician is named on its schedule of officers. We had hoped that the day when a hospital for women should be organized without a female physician on its roster had passed.

——Miss Emma Garrett sends us a summary of the work done in the Oral School for Deaf Mutes at Scranton, Pa. It furnishes striking evidence of the excellence of the Oral System.

——Dr. Burt G. Wilder, of Cornell University, details in a reprint before us the facts he has noted relating to what he designates the "Paroccipital Fissural Integer."

——Dr. Charles J. Lundy, of Ann Arbor, has issued as a reprint his address before the Alumni Association on "The Relations of the State and the Medical Profession."

——The value of Brücke's method in urine analysis is set forth in a reprint from the *American Chemical Journal* by Dr. E. M. Green, of Easton, Pa.

BOOK NOTICES.

Bright's Disease and Allied Affections of the Kidneys. By Charles W. Purdy, M. D., Queen's University. 8vo., 288 pages, with 18 illustrations. Cloth, $2. Philadelphia, Lea Brothers & Co., 1886.

That comprehensive term "Bright's Disease" is now taken to include so much, that there is no difficulty in writing a volume about it. That before us includes albuminuria, uræmia, acute and chronic scarlatinal and puerperal nephritis, and cirrhosis, lardaceous degeneration and cyanotic induration of the kidneys. The author gives a systematic description of these diseases, together with their pathology and treatment, as set forth by the most recent studies in this branch. The text is illustrated with a number of engravings from original drawings, chiefly representing the morbid anatomy of the kidneys. The type is clear, and an excellent index is added. We regard this as one of the best monographs which have appeared on the subject.

A Manual of Dietetics. By J. Milner Fothergill, M. D., Edin. 8vo., cloth. 255 pages. Price, $2.50. New York, William Wood & Company.

Dr. Fothergill is always a pleasant writer, and knows how to give a great deal of instruction without fatiguing his reader. All his wonderful powers are shown in the book before us. It is divided into two parts, the first discussing the various forms of foods, the second the special foods suitable to various periods of life and diseased conditions. We are surprised that he has not also added chapters on the food suitable in different climates and at different seasons—highly important points, which he omits. The author adopts in a general way Liebig's classification of "fuel foods" and "tissue foods," and collates the opinions of a large number of the best authorities. His own views are temperate and free from hobbiness.

A Guide to the Examination of the Nose, with Remarks on the Diagnosis of Diseases of the Nasal Cavities. By R. Cresswell Baber, M. D. Illustrated. Cloth. Pp. 163. New York: J. H. Vail & Co., 1886.

Diseases of the nasal cavity are so numerous, and have of late years excited so much attention that they are commencing to be a specialty in themselves. This is illustrated by the work before us, where the author finds material enough to fill nearly two hundred pages in describing the instrumental and other means of diagnosis applicable to this organ alone. After a short explanation of the anatomy and physiology of the nose, and laying down the symptomatology of its general diseases, the author takes up anterior and posterior rhinoscopy, palpation, etc. Wood-cuts of numerous instruments are inserted, and the volume is very carefully indexed.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

ILLEGAL PRACTITIONERS OF MEDICINE.

During the past six months the Philadelphia County Medical Society has been steadily and successfully ridding this city of the great horde of illegal practitioners who have, for years, been so boldly and so impudently trifling with the *real* ills, magnifying the imaginary ailments and growing rich, in many instances, upon the gullibility of a credulous public.

That the profession has undertaken this work, has contributed money to its prosecution, and has, in every way, aided the committee who have the work in charge, is but another evidence of the glorious nature of our profession, of the magnanimity of spirit, of the disinterestedness, of the catholic love of mankind and interest in its welfare, that seems to become so characteristic of the man who has a vocation for our profession.

Those who have suffered from these ignorant and audacious pretenders; those who have suffered both in body and in pocket are not the physicians; far from it, for so long as medical frauds flourish, so long will the consulting room of the intelligent physician be filled by those wrecks of humanity who have been landed upon the shoals of permanent ill health by the ignorant and consequently misdirected ministrations of the impostor and the charlatan.

As the incompetent plumber, employed to do the plumbing of a house in course of erection only makes more work for some good plumber who must needs be called in to remedy his inferior work, so the incompetent medical man only makes more work for the reputable and intelligent physician, who inevitably must, in the course of time, be appealed to for relief from the deplorable condition into which criminal ignorance has plunged its unhappy, but willing victim.

Therefore we again say that viewed from a pecuniary and selfish standpoint, the *quack* is the very best friend of the regular physician. This is no specious argument, intended to glorify our profession; it is the plain, unvarnished statement of a fact, that is amply substantiated by the experience of the majority of those who have, for a while, been beguiled by the flaming advertisements, and catching rascality and cunning of the quack.

But recently we heard of a man in this city, who was suffering from hernia. He read the advertisement of one of these frauds who promised a cure. He called upon him and was assured that he could be absolutely cured in four months; in fact, he was given

a written guarantee of cure, *prepared on a printed blank*, thus evidencing the habit of this wonderful leech to give guarantees. He was to pay eight dollars a month. To make a long story short, he visited his would-be executioner for three months, and paid him twenty-four dollars. About this time his hernia became strangulated, and he sought the services of a regular physician just in time to save his life. Upon recovery he called upon the leech and demanded the return of his money, as the *guaranteed* cure had not been accomplished. The reply was characteristic. "Not one cent will you get from me; all I want is your money; the world is full of just such fools as you;" and so it is unfortunately. This action, therefore, on the part of physicians, is an action directly opposed to their own financial interests, and is a philanthropic effort on their part to protect the gullible public from the evil consequences of their own gullibility, which they are doing at a sacrifice of their own interests, an example that we venture to say will find but few imitators in any other profession.

MEDICAL SOCIETIES.

The season is drawing near when the various medical societies throughout this country will be commencing their campaign for the fall and winter, and a word of suggestion may not be out of place. As a rule, the various county medical societies embrace in their lists of membership the great majority of the reputable physicians of the county, but it is an equally general rule that their meetings are attended only by a handful of the members.

A discussion on the International Medical Congress, or an attack on the American Medical Association, will pack the meetings to suffocation; but the ordinary scientific gatherings are disheartening, gloomy, and funereal affairs.

Why? Because the intellectual feast prepared is not sufficiently attractive to magnetize the members. Who, of late years, for instance, has heard the voice of Agnew in the hall of the Philadelphia County Medical Society? In former years, when he was comparatively obscure and unknown, he was ready enough to talk; but now, when *all* would flock to hear the pearls of wisdom that would drop from the lips of his mature experience, he is noted only by his absence. We pen these few words to remind our *distinguished* men that they owe a duty to the profession that they do not fulfil.

Notes and Comments.

Electrolysis for the Removal of Hairs.

Several very successful cases are reported in the *American Practitioner and News* by Dr. Samuel E. Woody, who says that the number of hairs to return and demand a second removal, will decrease with the skill of the operator and the thoroughness of the operation. He usually expects the return of about five per cent., but when these are in turn removed the cure is complete. It is always best to leave the finer or lanugo hairs, otherwise the face will have a bald, glistening appearance.

The essential instruments are a galvanic battery and a fine needle. The number of cells to be employed depends upon their strength, the delicacy of the patient's skin, and the distance between the poles when applied to the body. He formerly used from four to six zinc-carbon elements, but now employs twice that number of Leclanché (telephone) cells. These are placed in a closet, and connected by wires with the operating-table. More than a year ago they were charged with fifty cents' worth of sal ammoniac; and though furnishing electricity for door and signal bells about his office and residence, they are apparently as strong now as then.

For a long time he used the finest cambric needles, gold-plated, and has done some good work with them. Of late he has been using a very fine wire of iridium and platinum, which, being more pliable, follows the hair better, and is less likely to perforate the follicle. An ordinary surgical needle-holder, insulated by being covered with a piece of rubber tubing, may be used; but where much work is done, it is best to get one specially made of hard rubber, with a little strong button for breaking or closing the circuit. You should have the patient come only on bright days, for good light is necessary. She should be seated near a window, preferably in an operating or reclining chair, so that her face is nearly upon a level with the operator's eyes. A moistened sponge-holder connected with the positive pole of the battery is held in the patient's hand, while the needle-holder is attached to the negative pole.

The needle is now introduced for about one-eighth of an inch into the follicle down beside the hair. To do this accurately a sharp eye is necessary; and if the hairs are very small, he wears a jeweler's eye-glass. But most important is a steady hand and a

delicate touch. Possessing these, the operator can tell by the resistance encountered when the needle is piercing the dense skin or dropping into the follicle.

At the first sitting he has the patient close the circuit by grasping the sponge electrode, and thus avoiding the slight shock by making the connection more gradual than would be possible if he used the little spring button in the needle-holder.

Some Observations on the Theory of Bronchial Asthma, Viewed in the Light of the Pathology of Hay Fever.

Hay fever occurs in winter or spring; sometimes it occurs at sea or in the heart of a great city; sometimes when no pollen can be found in the air, it arises after a full meal, or in the middle of the night; sometimes it appears almost instantaneously under the influence of intense light, the heat of a great fire, the odors emanating from certain localities, plants, and animals; some particular place or position occupied in driving; or from emotions and vivid ideas. In an able and suggestive paper in the January number of *The American Journal of the Medical Sciences*, Sir Andrew Clark points out that in these and in all like cases there are clearly two main factors at work, a certain local or constitutional predisposition, and some immediately acting exciting cause. That some such predisposition exists is plainly proved from the fact that the exciting agents which produce the malady in one class of persons entirely fail to produce it in another; and that these exciting agents, in their relations to the persons acted upon by them, are in a remarkable manner specialized seems also proved by the circumstances that the emanations from a stable which in one person provoke a severe attack, produce in another, liable to hay fever, no sensible effect. And of the persons subject to this disease, it must be said that they are not always affected in the same manner by the same agent; for sudden intense light which may bring on an attack at one time will quite fail at another; and so we are compelled to conclude that the organism, or some particular part of it, varies so much in its conditions, that its relations to its environments are capable, without sensible structural alteration, of becoming completely changed.

When we inquire into the family and personal history of an individual subject to hay fever, we shall discover as the prominent point in it that the patient and his people are more or less "neurotic." There may be found among members of the patient's family the disease of which he is himself the subject, gout, such skin troubles as urticaria and eczema, migraine, neuralgia, epilepsy, and no inconsiderable sprinkling of pulmonary disease. But that which will be found the most widely, and will connect them all, will be a sensitive, an irritable, and an unstable nervous system.

In a series of propositions Sir Andrew sets forth what he regards as the teaching of a study of hay fever concerning the pathology of bronchial asthma, holding that it is a neuro-vascular trophic disease, and has its roots in a special vulnerability of the respiratory mucous membrane, of the respiratory nerve centres, and of certain portions of the sympathetic.

The Influence of Drugs on Nurslings when Administered to their Nurses.

The Paris correspondent of the *Brit. Med. Jour.*, says that Fehling has recently, by experiment, studied the effects on nurslings of certain drugs given to the women who suckled them. When doses varying from two to three grammes of salicylate of soda were administered to the nurse, every time that a child was suckled within an hour after the administration of the dose, the salicylate appeared in its urine. After an interval of twenty-four hours there remained no trace of the drug. When the child was suckled too soon after the medicine had been taken, the salicylate could not be found in its urine. Elimination was completed at the same time in the mother and the child. With iodide of potassium the results were the same. The milk, when analyzed, gave the characteristic reaction. In the infant, elimination lasted twenty-two hours; in the mother, forty-four. After twenty-four hours, the milk still contained iodide of potassium. With ferrocyanide of potassium, reaction was very pronounced in the maternal urine, but absent in the child's. Prolonged applications of iodoform upon vaginal and vulvar wounds of women in parturition, after prolonged use, generally resulted in iodine being found in the milk and urine of the mother, but not always in the urine of the infant. The child was never indisposed, even when iodoform was used, to dry up the umbilical cord. There was only a small quantity of mercury transmitted through the milk of a nursing mother, and its presence was not constant. It appeared that the food of wet nurses—even acid fruit-juices and vinegar—

had no influence on their nurslings. Thornhill had stated that he observed prolonged sleep occur to children after administering to their wet nurse such narcotics as tincture of opium in doses of from 20 to 25 drops. Fehling observed neither prolonged sleep nor constipation in the children. Hydrochlorate of morphine or chloral, in tolerably strong doses, did not affect the sucklings.

Renal Irritation from Pure Terebene.

A correspondent writes to the *Brit. Med. Jour.* to ask his professional brethren whether they have ever noticed severe nephralgia and other evidences of renal irritation follow the use of "pure terebene." He has lately had under his care a case of bronchiectasis, in which he tried all the stock remedies, such as creasote, eucalyptol, iodine, phenol, iodoform, tar, sandal-wood oil, and, lastly, "pure terebene," to try and diminish the secretion and lessen the almost gangrenous odor of the sputa. He thinks he may safely say that they all practically failed to accomplish what he intended, even though the doses were pushed. "Pure terebene" was the last experimented with, and when his patient was taking from twenty to twenty-five minims four or five times during the twenty-four hours, he suddenly developed most intense nephralgia, and the urine became scanty, high-colored, and distinctly albuminous. There had been traces of albumen before, but it was distinctly increased at this time. There was no reason to suspect renal "colic" due to other causes. The terebene was omitted, and gradually the symptoms subsided. After the lapse of three weeks, "pure terebene" was again begun to be taken, and, as the doses were increased to the same quantity as before, a repetition of the nephralgic symptoms occurred, but less marked than before, and gradually a tolerance was established. Ordinary turpentine, it is well known, will produce symptoms of renal irritation; may it not be possible that its isomeric brother, "pure terebene," also will occasionally produce somewhat similar symptoms?

"Hot Eye" in Association with Gout.

Mr. Jonathan Hutchinson, in a note on this subject in the *Brit. Med. Jour.*, says:

The following item of evidence is, I think, valuable in reference to the connection of certain diseases of the eye with gout. A gentleman named W. consulted me on account of attacks of irritability, first of one eye and then of the other. The eye would become a little red, and feel as if he had sand in it. The attacks would usually last from two to four days, but they recurred very frequently, and were a source of much annoyance. He had made his own diagnosis before coming to me, and remarked, "I never knew what they meant until a year ago I had an attack of gout in the great toe." He was of dark complexion. He had, of late, been very careful in his habits, but he inherited gout strongly on both sides. Having noticed the identity of names, I asked him if he was a relative of a certain Dr. W. "Yes," he said, "I am his first cousin, and there is the same inheritance in both of us." In the latter case the patient, then a young man, lost one eye from recurrent attacks of iritis, and had much damage to the other. His case is given in the series which I have published, illustrating the peculiar form of destructive iritis which goes with hereditary gout. Thus the two cases support each other, and afford strong evidence, firstly, as to the connection with inheritance of gout tendencies, of the destructive form of iritis; and, secondly, with personal proclivity to gout of the "hot eye."

Potassium Chloride.

Speaking of this drug before the last meeting of the American Medical Association, Dr. Asa F. Pattee, of Boston, said that exudations after inflammation with effusion of lymph, particularly pelvic cellulitis, have quickly disappeared under its use. In glandular enlargements, in his hands, it has been of more benefit than calcium chloride or the iodine compounds. In stomatitis of pregnant women, or from mercury, it is equal to the chlorate. In ovarian neuralgia, with nervousness and menstrual headache, accompanied with wakefulness, this salt has given better results than the bromide or ammonium chloride. When combined with corrosive sublimate it is one of the best preparations for syphilis. He usually gives it as follows:

R.	Potassii chloridi,	ʒij.
	Hydrargyri chlor. corros.,	gr. j.
	Aquæ.,	ʒiv.

M. S.—10 to 20 drops every two hours in wine glass of water.

This preparation he has used almost exclusively in the treatment of syphilis in both its acute and chronic stages, and the result has been most satisfactory. The tincture ferri chloridi is much improved in its therapeutic action when given with potassium chloride.

It is his desire that those of our profession who have not used the potassium chloride may investigate its therapeutic action, of which he can assure them it will verify his statement. The dose will range from 20 grains to 2 drachms in twenty-four hours, well diluted with water.

Digitalis in Bright's Disease.

In the course of a paper on the "Cardiac Complications of Bright's Disease" in the *Med. News* (July 31), by Dr. James Whittaker, the following occurs:

"It is indeed a fatal mistake to administer digitalis while the heart is still adequate to the work of compensation. Neither uræmia nor albuminuria, of necessity, calls for digitalis. Dropsy is, in general, the best indication, because dropsy indicates inadequate compensation on the part of the heart, which is also, and often in the absence of dropsy, manifest in the condition of the pulse. Other symptoms of Bright's disease are infinitely better treated by appeal to the skin, wherein prolonged hot baths outrank all other remedies.

"When the heart has fully responded to digitalis, and its further administration is contraindicated by the state of the pulse, tonic effects are best sustained by arsenic and iron; and when, finally, the heart no longer responds to digitalis, resort must be had for relief of symptoms to alcohol and morphia. But this day may be long delayed by a vigilant supervision of the heart, which, next to the secretion directly from the kidneys, most distinctly gauges the stage of the disease."

Cocaine in Mercurial Stomatitis.

In the *Monatsch. f. pr. Dermat.*, 1886, No. 6, Dr. Max Rockhart recommended cocaine against the painful swelling of the gums, the tongue, and the parotis and neighborhood, all signs that frequently accompany salivation and greatly disturb nutrition.

B. employed with decided success a 10 to 20 per cent. solution of cocaine, which is applied with a camel's hair brush a few minutes before a meal. In mild cases a 5 per cent. solution seemed to suffice. In all cases the improvement was very rapid, and the patients felt much better and could swallow easier.

Immediately after the application the brush must be disinfected in diluted carbolic acid, as the bacteria contained in the buccal cavity greatly reduce the usefulness of the cocaine solution, which is decomposed.

Should further observations prove the reliability of cocaine in these cases, it would be a boon to all patients who have to undergo a thorough mercurial treatment on account of constitutional lues.

A Fungus Developed in the Human Saliva.

M. Galippe made known the following facts at a recent meeting of the Paris Academy of Medicine. After having purified saliva by means of Pasteur's filter, M. Galippe observed, at the lower extremity of the filter, which was not in contact with the fluid, a fungus composed of tubes and spores of mycelium. Following the advice of Professor Cornu, M. Galippe cultivated this fungus in the cells of Van Tieghem, and observed that the fungus was neither an *Aspergillus* nor a *Penicillium*. This fungus, which had neither been described nor represented, belongs to the Moniliæ family. M. Galippe proposed to give it the name of *Moniliœ sputicola*. M. Charcot repeated these statements at the Academy of Sciences, in the name of M. Galippe.

Drunkard's Epilepsy.

The *Med. News* (July 31) tells us that in view of Magnin's assertion that in France the frequent cases of epilepsy occurring in drunkards are due, not to alcohol but to absinthe, Moeli has reviewed the German statistics of the subject, which may be thus summarized:

In Germany, 36 to 40 per cent. of the subjects of delirium tremens are also victims of epileptic attacks. An attempt to determine whether the occurrence of such attacks was correlated with the abuse of any special kind of distilled liquor was unsuccessful, but it was found that in twenty-six almost exclusively beer and wine drunkards only one was epileptic.

Corrosive Sublimate in Surgery.

In concluding a paper in *The Fort Wayne Journal of Med. Sci.*, Dr. J. G. Buchanan formulates as follows: 1st, that extreme caution should be observed if sublimate solutions are used on granulating surfaces, particularly cavities, the peritoneal surface and the parturient canal; 2d, that when large surfaces are to be irrigated, the strength be not greater than 1 to 4000 or 5000; 3d, that, in all important cases, to secure perfect solution, the sublimate be first dissolved in alcohol, and this diluted with water, or, when this is not practicable, to have the solution

strained; 4th, it should be added that it has been noticed that nephritis and anæmia predispose patients to poisoning by corrosive sublimate.

Exudative Retinitis in Bright's Disease.

Dr. E. Gruening, of New York, told a recent meeting of the Ophthalmological Society that he had collected over one hundred cases of this affection, and he found that none of them had lived over two years after the diagnosis of retinitis albuminurica had been made. In this class of cases he has included only those in which the typical stellate changes were seen in the maculæ of both eyes. He lately had seen this appearance in the macula of one eye in a patient who presents no evidence of Bright's disease. This was the first time he had seen this exquisite change without signs of renal disease.

Correspondence.

A Case of Disease.

(*Concluded from page* 187.)

For a moment I was carried away by these thoughts. Salicylic acid, carbolic acid, corrosive sublimate (an old acquaintance), and a host of new, partially tested remedies, pressed their claims for employment; not because of proved utility, but that "they are much used in the hospitals," that "they are all the rage in Philadelphia," that "Dr. Koch has proved that all diseases are caused by germs, and therefore all remedies should be germicides." Then, too, "blood-poison," that term so convenient to give as a cause of death, when we have been groping in the dark, wholly ignorant of the disease we have failed to cure, presented itself, and I was the nearest thing possible to being led astray by these fine phrases, so often seen in medical journals and heard from the lips of my young friends, who keep me "posted" on the changes which follow each other so rapidly now, when a shriek from my patient brought me again to a consideration of her situation and to a conviction that I was confronted with a disease of the brain or its membranes—I certainly did not know which, for I have never yet heard of any symptom by which in the early stage the one is distinguished from the other. Nor did I care, so far as treatment was concerned; not that the case was a light one, for it was to me one of the most severe I had ever seen in one so young. The responsibility weighed heavily upon me, because I was not confident of the proper course to pursue, and because fifty years ago I had a case much resembling this, but being young in practice, relied on *medicine* for the arrest of the disease, and my patient died as speedily as did Dr. Wilson's.

As the preponderance of symptoms seemed to point to brain disease, the question arose, how shall I treat it? When asked by parents, in such a case, "What is the matter?" it is easy to say it is an "affection of the brain," while, at the same time, we fail to see clearly what is going on there, and what further will take place if its progress be not arrested. We ought to know exactly what is meant by inflammation of the brain, or of its membranes, and be prompt to use the proper means to check the disordered process, or we shall prescribe in vain. We all know what large vessels carry blood to the brain, and that the pia mater seems but a mesh of small blood vessels. From some cause a congestion has taken place, the blood in the arteries is driven up against the congested part, but being unable to clear the passage, more and more of the small arteries become blocked, and thus the congestion spreads to more and more of the brain, or its membranes, and this congestion results in inflammation. Is not every inflammation produced in that way?

My patient had been ill twenty-two hours; it had been seventeen hours since I was called; my practice had been trifling; apparently useless, but not careless or indifferent. The impulse was to give sulph. morph. to allay the severe pain, but I feared to do this lest it might afterward be difficult to distinguish its effects from the dullness produced by the disease. There she lay before me, pale as death, her eyes closed against the light, moaning and occasionally crying aloud; her pulse disturbed and apparently weak, with but little increase in frequency. The operations inside the skull then seemed clear to me. The area of distended and obstructed vessels was increasing, and the irritation in the parts first obstructed becoming more intense, and no *medicine* in our almost endless catalogue which can with certainty unload the blocked vessels. It was to me a moment of supreme anxiety. My determination was taken, and her arm "tied up" without resistance from her, indeed without her noticing it, and eight ounces of blood were drawn, when the pulse became still more indistinct, and on calling her, she was evidently duller than before. The parents thought they saw a change for the worse, and we had bustle, confusion and crying, up

stairs and down. How intensely anxious I was, and how needful it was to exhibit composure, need not be told. The precaution had been taken to elevate her head by pillows before bleeding her; the removal of them and sprinkling her face with cold water revived her. In an hour she was better than before the bleeding. A bladder of ice and water was placed on the pillow for the upper part of the neck and the back part of the head to lie upon, while another was placed on the top of the head. Saw her again at 9 a. m.; pulse a little firmer than before she was bled. Ice to be continued; lemonade to be given as drink, if any can be retained; for, until she was bled, she had not been able to retain any fluid for a single minute, and this was the principal reason of my doubt as to the seat of the primary affection, whether in the brain or stomach. Saw her next day at 8 a. m. Those about her thought her "a little better." Pulse 80, and more distinct, and the face red, though, until she was bled, it had been very pale. Since the bleeding she has taken drink freely without vomiting, though before, from the onset of the disease until six o'clock p. m. yesterday, when bled, she had vomited every spoonful of water or whatever else had been given her. This fact made the case plain to me. I then knew that the cause of the disorder of stomach was in the brain, and that the bleeding had partially relieved the latter organ; enough, indeed, to allow proper innervation to the stomach: but the pain was still present in the forehead to a degree that caused her to say—after the ice had been removed for only a short time—"put on the ice, or I shall go crazy." The ice was applied, and 5 grs. calomel given, to be followed by epsom salts in lemonade. A messenger was sent to Norristown for a leecher, and with directions to ask my nephew, Dr. E. M. Corson, to be with me at 2 p. m. I longed for some one to whom I might talk about the case, to advise me, even if I should not be willing to act on his counsel. We were there at the time fixed; the bowels had been moved, she answered questions better, the face was slightly red, pulse discouraging to my consultant because of its apparent weakness, but yet he seemed willing to bear part of the responsibility of drawing blood by leeches. It was due to him that I should give reasons for drawing more blood from one whose pulse was apparently so weak and whose face was so pale. I said, "Two days ago this child was well, now she has pain in the head because of congestion and commencing inflammation inside of the skull—it is hard for me to say whether in the brain substance or in the meninges; most likely the latter." He smiled affably at this confession of ignorance, of which a graduate of yesterday would be ashamed. I resumed, "Professor George B. Wood, whose graphic and accurate descriptions of the symptoms of diseases have furnished to authors on 'Medical Diagnosis' nearly their whole stock in trade, and which they have appropriated without acknowledgment in speaking of cerebritis, says: 'From meningitis, the disease, as already described, is distinguished by a very uncertain line.' . . . . . 'Very frequently the symptoms are so intermingled that a positive decision is impossible, and the physician must be guided by probabilities alone in the forming of his opinion.'" I added, while it was doubtful to me at first whether the primary affection was in the stomach or in the brain, I now *know* that it was in the latter, because since the bloodletting and the ice partially relieved the brain, the stomach rejects nothing. Many physicians in cases of cholera infantum have labored in vain to arrest vomiting by remedies applied to the stomach, but when applications of ice, or ice water by affusion, or leeches, or blisters, were made to the head, the vomiting and even the diarrhœa sometimes soon ceased. So now, as I know this is a congestion somewhere in the head—for practical purposes it makes little difference where—which will pass rapidly into inflammation if not arrested; and as I have no fear of debility, and know with Dr. Wood that, "if the pulse were the sole guide, so little excited and so weak is it in many instances that stimulants rather than depletion might be deemed necessary," I therefore disregard this weak pulse, and the leeches must go on. Three large Italian leeches were applied at each temple. They drew blood copiously. The wounds bled freely for an hour, then pressure was applied to stop the flow. Visit at 6 p. m., two of the wounds have oozed freely since 4 p. m. The cloths on that side of the neck are very bloody. Her face is paler than before the leeching, but she has less pain in the head; at least she is a little brighter. Directed $\frac{1}{12}$ gr. sulph. morph. and 5 grs. bro. pot. every 3 hours through the night if needed to procure rest, and a bladder of ice and water laid under the head and one on the top of the head.

14th, 9 a. m. Pulse 80, soft, and more distinct; child pretty comfortable, but the pain in the forehead still pretty bad; has slept some, has had no food at all thus far; applied a blister plaster to the whole forehead;

morph. and bro. pot. continued if needed; urinates freely.

15th, 9 a. m. Blister acted well. Pain in forehead much better. Omit medicine, continue ice; pulse 88; more heat of skin. Bro. pot. and morph. resumed, to relieve restlessness.

16th. 9 a. m. Pulse 84; appears comfortable. Here let me call attention to the fact that until now—a period of 104 hours—she has had no food. We offered her none. Why? We were combating an acute inflammatory disease of the brain, we believed the stomach was rejecting even water. We were not, as is now very common, stuffing the patient with food, *in the early stage*, in order that it might be made strong to bear the more advanced stages, but were so acting as to cut short the disease in its first stage, so as to avert the fatal advanced stage. This same mode of forcing food on pneumonia patients is in high repute with those who trust to the "new medicines" in that disease. They stuff the patient from the beginning, so that he may be strengthened to bear the last stage—a stage which he escapes by dying before it arrives. To a patient suffering with *any* severe inflammation, food is nauseous for many days—never needed—always useless, if not positively injurious. After the first few days it can be tolerated, even if not craved; then I allow it. So now in her fourth day of illness I direct milk to be taken occasionally. She went right on to improve; convalesced rapidly without stimulants; and on the 27th I left her well and happy, with no advanced stage confronting her.

HIRAM CORSON, M. D.

Conshohocken, Pa.

NEWS AND MISCELLANY.

American Dermatological Association.

The tenth annual meeting will be held at the Indian Harbor Hotel, Greenwich, Ct., August 25, 26, and 27.

PROGRAMME.

First Day, August 25.

Business meeting (with closed doors) at 9:30 a. m.

Report of Council.

Appointment of Nominating and Auditing Committees.

Proposals for Active and Honorary Membership.

Miscellaneous Business.

Morning Session at 10 *A. M.*

Address by the President, Dr. Edward Wigglesworth.

1. Report of a Case of Lymphadenoma (Mycosis fongoide) and Autopsy, by Dr. G. H. Fox.

2. Note relative to the Bullous Eruption Occurring after Ingestion of Iodine Compounds, by Dr. J. N. Hyde.

3. Erythanthema Syphiliticum, by Dr. E. B. Bronson.

4. "Rötheln," by Dr. I. E. Atkinson.

Adjournment at 1:30 p. m.

Evening Session at 8 *P. M.*

5. Precocious Gummata, by Dr. R. W. Taylor.

6. Clinical Notes on Scabies, by Dr. F. B. Greenough.

7. Clinical Observations regarding the Value of Resorcin, Icthyol, and Lanolin in Cutaneous Diseases, by Dr. H. W. Stelwagon.

8. Trophoneurosis of the Skin, by Dr. G. H. Tilden.

Adjournment at 10 p. m.

Second Day, August 26.

Business meeting (with closed doors) at 9:30 a. m.

Report of the Treasurer and Auditing Committee.

Report of the Nominating Committee and Election of Officers.

Election of Active and Honorary Members.

Selection of time and place of next meeting.

Miscellaneous Business.

Morning Session at 10:30 *A. M.*

Report of the Committee on Statistics.

9. Native Plants Injurious to the Skin, by Dr. J. C. White.

10. Report of Two Cases of Dermatitis Herpetiformis, by Dr. A. Van Harlingen.

11. A Few Additional Notes on Psoriasis, by Dr. F. B. Greenough.

12. Report of a Case of Exfoliative Dermatitis, by Dr. W. A. Hardaway.

Adjournment at 1:30 p. m.

Evening Session at 8 *P. M.*

18. A Clinical Study of Scleroderma, by Dr. J. E. Graham.

14. A Case of Carcinoma Cutis, by Dr. L. N. Denslow.

15. Keratosis Follicularis, by Dr. P. A. Morrow.

16. Surgical and Obstetrical Scarlatina, by Dr. I. E. Atkinson.

Adjournment at 10 p. m.

Third Day, August 27, *Morning Session at* 10 *A. M.*

17. Notes on Drugs, by Dr. H. G. Piffard.

18. Cartilaginous Tumors of the Skin, by Dr. A. R. Robinson.

19. Remarks and Queries on and as to Relative Frequency of Moles and their Pathological Changes on the Head and Face, by Dr. S. Sherwell.

20. An Unusual Form of Tuberculosis of the Skin, by Dr. G. H. Tilden.

Retirement of old and induction of newly elected officers.

Adjournment at 1 p. m.

P. O. address of the place of meeting: Indian Harbor Hotel, Greenwich, Ct. Trains leave New York for Greenwich, Grand Central Station, 42d St., at 9:17, 10:05 a. m., 12:00 m., 3:02 [4:00, 4:45, 5:40] p. m.

The trains in brackets are express trains.

American Otological Society.

At the nineteeth annual meeting of this society, held at New London, Conn., July 20, 1886, the following papers were read: "Acute and Chronic Purulent Inflammation of the Middle Ear Tract, and their Complications," by Dr. S. Sexton, of New York. "A new Operation for the Radical Cure of Chronic Purulent Inflammation of the Middle Ear Tract," by Dr. S. Sexton, of New York. "Painless and only Slightly Painful Ulceration of the Membrana Tympani, Probably of a Tubercular Nature," by Dr. A. H. Buck, of New York. "Certain Technical Details Relating to Operations on the Mastoid Process," by Dr. A. H. Buck, of New York. "Fatal Termination of a Case of Sclerosing Mastoiditis after Chiselling of the Bone," by Dr. H. Knapp, of New York. "A Case of Abscess of the Mastoid Cells in which the Chief Indication for Operation was Elevation of Temperature," by Dr. O. D. Pomeroy, of New York. "On two Cases of Chronic Purulent Inflammation of the Attic of the Tympanum, with Perforation of the Membrana Flaccida, Treated with Peroxide of Hydrogen," by Dr. Charles H. Burnett, of Philadelphia. "In the Physiology of Hearing is there an Overlapping of each Auditory Field the Same as in Binocular Vision," by Dr. William S. Little, of Philadelphia. "Two Cases of Ear Disease due to Traumatism," by Dr. Gorham Bacon, of New York.

The following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—Dr. J. S. Prout, of Brooklyn.

Vice-President.—Dr. Samuel Sexton, of New York.

Secretary and Treasurer.—Dr. J. J. B. Vermyne, of New Bedford, Mass.

Committee on Membership.—Drs. Gorham Bacon, W. S. Little, and E. W. Bartlett.

American Ophthalmological Society.

At the twenty-second annual meeting of this society, held at New London, Conn., July 21st and 22d, the following papers were read: "Pyogenic Micro-organisms, with Demonstrations and Experiments," by Dr. H. Knapp, of New York. "An Analysis of One Hundred Cases of Exudative Retinitis Occurring in the Course of Bright's Disease," by Dr. C. S. Bull, of New York. "Thrombosis and Perivasculitis of the Retinal Vessels," by Dr. George C. Harlan, of Philadelphia. "A New Test Type," by Dr. William S. Dennett, of New York. "The Possible Retardation of Retinitis Pigmentosa in the Young," by Dr. Hasket Derby, Boston. "The Equivalence of Cylindrical and Sphero-cylindrical Lenses," by Dr. Edward Jackson, of Philadelphia. "263 Cases of Cataract Extraction with Particular Reference to the After-treatment," by Dr. George Strawbridge, of Philadelphia. "Cataract Extraction without Iridectomy," by Dr. H. Knapp, of New York. "Report of Fifty Cases of Cataract Extraction," by Dr. David Webster, of New York. "Death of a Patient on the Fifth Day after the Extraction of a Hard Cataract," by Dr. Henry D. Noyes, of New York. "Some Medico-Legal Cases," by Dr. B. Joy Jeffries, of Boston. "A New Series of Loose Wools for the Scientific Detection of Subnormal Color-perception (Color-blindness)," by Dr. Charles A. Oliver, of Philadelphia.

Inoculation for Yellow Fever.

The *Brit. Med. Jour.* says that the modern expedient for settling knotty points in sci: ence is to appoint a commission; success, it is true, has not uniformly attended this method, and the reports, if not polemical, are generally colorless. Yellow fever is the disease which is now to be investigated in this way. A few years ago Dr. Domingos Freire announced that he had prepared a vaccine which preserved the vaccinated from yellow fever; his method of experimenting, however, did not commend itself to the bacteriologists; and M. Rebourgeon, who had been trained in M. Pasteur's laboratory, was sent out to Rio de Janeiro to guide Dr. Freire into the right way. The papers since

published by these two experimenters confirmed the earlier claims, and M. Rebourgeon has returned to Paris to convince the skeptics; he informed the Société de Biologie at its meeting on May 22, that, during the recent epidemic, 6,000 persons had been inoculated, of whom not one suffered from the disease: and that, in seven cases where patients were inoculated while suffering from the disease, recovery took place in every instance. The Society appointed a commission of five, including MM. Brown-Sequard and Cornil, to study the method. In the United States, moreover, the demand for a commission has been backed by the American Medical Association.

Utilizing the Mosquito in Vaccination.

A curious sort of vaccination has been invented by Dr. Charles Finlay, of Havana, for protection against yellow fever. It has long been supposed that the poison of yellow fever might be conveyed by inoculation, although no one appears to have wished to have the experiment tried on himself; but Dr. Finlay has applied to nature for a lancet more delicate than any human tools, and seems to have succeeded in this way in proproducing a mild form of yellow fever by inoculation directly from a yellew fever patient. The process itself is simple enough. A mosquito is persuaded to bite a person suffering from ordinary yellow fever, and is soon after brought to a healthy person, whom, when his appetite returns, he bites without that previous wiping at the mouth which would be thought desirable in polite society. Without dwelling upon particulars, it is sufficient to say that the yellow fever contagion was found, in six cases out of eleven, to be communicated to the healthy person, who, after the period of incubation had passed, became affected with various symptoms characteristic of yellow fever in a mild form. According to the *Lancet*, Dr. Finlay believes that this mode of inducing a prophylactic variety of yellow fever may be found very valuable in practice.

How Far Can One See?

The *Popular Science News* says that a discussion is going on in Europe concerning the distance at which large objects on the earth's surface may be visible. Emil Metzger mentions that he once saw, with some difficulty, Keizerspickt, in Sumatra, when distant 110 English miles; and he also made out Gug Merapi, in Java, when 180 miles away. From the Piz Muraum, near Dissentis, E. Hill has seen Mont Blanc, the intervening space measuring about 110 miles. J. Starkie Gardner states that Mont Blanc is visible from the Piz Langard, though distant about three degrees. In Greenland, Mr. Whymper beheld a mountain from which he was separated by 150 miles; and from Marseilles, Zuch saw Mount Canigon at a distance of 158 miles. The whole range of the Swiss Alps has been looked upon by J. Hippisley while 200 miles away, while Sir W. Jones has affirmed that the Himalayas have appeared to view from the distance of 224 miles.

Electric Light for Laboratory Investigation.

M. de Lacaze-Duthiers uses, in his Sorbonne laboratory and in his zoölogical stations at Roscoff and Banyuls, an electric lamp constructed by Trouvé, which would also be useful in much chemical, botanical, and mineralogical work. It is composed of a cylindrical glass vessel, beneath which is a mirror of silvered glass. There is a silvered parabolic covering, in the centre of which is suspended an incandescent lamp. The vessel is filled with sea-water containing corals, polyps, sea-worms, and other objects which can be examined by the aid of magnifying glasses, the whole mass being thoroughly illuminated, as in the brilliant experiment of the illuminated fountain. The apparatus can be readily modified for the study of fermentation, and for dissecting, with great ease, nervous filaments of the greatest delicacy, which are hardly visible in the broad light of day. The generator of electricity is Jamin's universal automatic battery, weighing less than three kilogrammes.

Media Medical Club.

The Media (Delaware county) Medical Club held its regular semi-monthly meeting on Friday evening, August 6, at the residence of Dr. H. Stelwagon. Fifteen gentlemen were present, the president, Dr. Stelwagon, in the chair. The subject for special discussion was "The Detection of Oleomargarine from Butter." A sample of oleomargarine and two samples of different grades of butter were passed around and tested by each gentleman present, whose verdict was recorded. There was some diversity of opinion, though the majority were able to properly differentiate the products. It was then suggested that the accuracy of the sense of smell should be tested, and this proved to be the best means of detecting the oleomargarine, for only one of those present failed in

making a correct diagnosis. The genuine butter had a "buttery" smell, while the oleomargarine was devoid of odor, or at the best, had a smell of "grease." After a musical entertainment by Dr. Dickerson, the club adjourned.

Purity of Drinking Water.

The *Chemist and Druggist* says it is often required to give a quick indication of the freedom, or otherwise, of water from organic products. The rough and ready permanganate test cannot be relied upon. Most organic bodies, that is those containing nitrogen, are converted into ammonia, which is ultimately oxidized into nitrous and nitric acids. The detection of nitrous acid, therefore, is important, since its presence is sufficient to condemn any water for domestic purposes. Mr. C. C. Howard has suggested a ready test, which is as follows: Into a test-glass place some of the water (not more than 50 c.c. or ℥iss.), and add a drop of hydrochloric acid, then a drop of sulphuric acid, and one of a solution of naphthylamine hydrochloride. If the water does not contain more than 1 in 100,000,000, after standing for ten minutes it should not show more than the faintest tint of pink color.

Wild Beasts and Snakes in India.

During the past year, wild beasts and snakes have been unusually destructive to human life in the central provinces of India, there having been an increase of 262 in the number of persons killed, as compared with the preceding year. Of wild beasts, tigers, of course, were the most destructive, their victims numbering 110, against 98 in 1884, while the number of tigers killed was only 221, against 260. The deaths from snake-bite last year amounted to 1,066, against 797 in 1884, while only 1,997 snakes were killed, as compared with 2,378. In an official note on the subject, it is observed that there has been a "satisfactory increase" in the number of wild animals destroyed; but this increase is due to the larger number of bears, wolves, and hyenas destroyed.

Thinking and Working.

The *Popular Science News* tells us that in our present system of education—now happily passing away for a better one—we want one man to be always thinking, and another to be always working; and we call the one a gentleman and the other an operative; whereas the workman ought often to be thinking, and the thinker often to be working, and both should be gentlemen in the best sense. As it is, we make both ungentle, the one envying, the other despising, the other; and the mass of society is made up of morbid unhealthy thinkers and miserable workers. It is only by labor that thought can be made happy; and the professions should be liberal, and there should be less pride felt in peculiarity of employment, and more in the excellence of achievement.

Danger from Umbrellas at Sea.

In these days of electric lighting, one is often in the neighborhood of dynamos, and, however short the time of exposure to their influence, pocket knives, and the steel in watches and umbrella frames, may become powerfully magnetized. On board the *Princess Beatrice*, the helmsman lately observed that the compass was agitated. On examination, he found that the needle was affected by the magnetized steel mounting of a parasol in the hands of a lady who was walking upon the bridge. If the lady had been at rest, so that nothing would have shown the abnormal deviation, the ship might easily have been steered out of its course, and thus been exposed to dangerous accidents.

Where Male Nurses are Best.

In concluding a lecture on Rectal Fistulæ and Hemorrhoids, in the *Brit. Med. Jour.* (July 24), Dr. Richard Davy says: "Let me give you my own opinion on the very great value of male attendants as nurses in these cases of hemorrhoids in men, or in any case of operation on or near the generative or perineal portion of a man's body. Surgeons are not sufficiently explicit on this point; for such cases need constant cleansing and occasional lifting; and, excellent as women nurses may be as subalterns in easy forms of general surgery, or in cases of their own sex or children, yet commend me to the trained and disciplined service of a male attendant as my non-commissioned officer, in operations such as I have now brought before you.

Lemonade Tablets.

The following is a German formula:

℞.	Powdered white sugar,	800 grammes.
	Bicarbonate of sodium,	100 "
	Tartaric acid,	100 "

To be intimately mixed, flavored with five drops oil of lemon, and made into a mass with two hundred grammes alcohol. The mass is now pressed into any convenient

mould (previously well oiled with melted cacao butter), and dried well in a drying closet. The lozenges must weigh about twenty grammes, which will be sufficient for a tumbler of water. Other flavors may be obtained by substituting the above-mentioned quantity of oil of lemon with two drops of oil neroli, or five drops oil of sweet orange, or two drops attar of rose.

A Fool Defined.

Erasmus Darwin defined a fool as "a man who never tried an experiment in his life." There is no escape from a definition like this, as there is from such a saying as J. S. Mill's, "Every fool is a conservative." Mill could logically say it did not follow that "every conservative is a fool,"—which, let us hope, gave great comfort to the conservative mind. We cannot, however, say that Erasmus Darwin's definition leaves even one out who never tried an experiment; for a true definition does not err either in excess or in defect. This definition, therefore, asserts that every man who has tried no experiment in his life is a fool, as certainly as it asserts that no fool ever tried an experiment.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE WEEK ENDED JULY 31, 1886.

Long, W. H., surgeon. Granted leave of absence for fifteen days, July 30, 1886.

Sawtelle, H. W., surgeon. To proceed to Portland, Oregon, and Port Townsend, W. T., as inspector, July 29, 1886.

Devan, S. C., passed assistant surgeon. Granted leave of absence for ten days, July 26, 1886.

Fattic, J. B., assistant surgeon. Granted leave of absence for twenty-nine days, July 26, 1886.

Lead Pencils.

Even as late as the sixteenth century chiefly pencils made from lead and tin were used for marking or writing, and deserving more properly the appellation of "lead" pencils than what we now call so. Conrad Gessner called attention in 1565 to the use of black-lead for writing purposes, but still in 1667 black-lead was so little known that it did not even have a Latin name, until Merret proposed to call it *Nigrica fabrilis*. Already in 1683 the black-lead pencils were encased in cedar or pine wood.

The Sequel of Two Great Operations.

At a recent meeting of the Basle Medical Society, Professor Socin, of Basle, showed the stomach from a woman in whom he had performed first, resection of the pylorus, and, subsequently, a year later, gastro-enterostomy. The patient died, from return of malignant disease, eighteen months after the second operation.

Items.

—A cigar contains acetic, carbolic, formic, butyric, valeric, prussic, and propionic acids, also creasote, ammonia, sulphuretted hydrogen, pyridine, viridine, picoline, and rubidene, to say nothing of cabbagine and burdockic acid. That's why you can't get a good one for less than five cents.

—"I say, Gov'ner, how do yer sell ammunition?" "What's up, then? Are you going to enlist as a soldier?" "No; that's what my girl told me to get for the baby; it is sold in boxes." "Is it fuller's earth or violet powder? How are you going to use it?" "If you give me the world I couldn't tell you." "Was it magnesia?" "Hi, that's it; I am glad you thought of that. Well, there is no difference, is there? Give us a penn-'orth."

—An explosion of nitro-glycerine occurred recently in the mixing house of a dynamite factory in New Jersey, whereby ten men lost their lives. Only little bits of their bodies were afterward found. The woodwork of the house was mostly reduced to fine powder, and small craters in the earth marked points where most of the nitro-glycerine is supposed to have been. The explosive force of this compound seems almost incredible to those who have never witnessed its effects.

OBITUARY NOTICE.

ELI E. BATEMAN, M. D.

At Cedarville, N. J., on Friday, July 23, Dr. Eli E. Bateman died, aged 80 years and 9 months. All of Dr. Bateman's life was passed in the place where he died, except the period occupied in obtaining his education. He was graduated M. D. from the University of Pennsylvania in the class of 1832. Commencing practice immediately in his native place, he encountered the Asiatic cholera, as it then prevailed. In all the years that followed, he was held in high esteem as a skilful practitioner and a courteous Christian gentleman. He was interred in the grounds of the First Presbyterian Church, with which he had long been connected.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

THE BEST

—ANTI-SEPTIC—

For Internal and External Use.

LISTERINE

LAMBERT

PHARMACAL COMPANY.

ST. LOUIS.

FORMULA.—Listerine is the essential Antiseptic constituent of Thyme, Eucalyptus Baptisia, Gaultheria, and Mentha Arvensis in combination. Each fluid drachm also contains two grains of refined and purified Benzoboracic Acid.

ANTISEPTIC, PROPHYLACTIC, DISINFECTANT, NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC, AGREEABLE, STRICTLY PROFESSIONAL and SCIENTIFIC.

Listerine comes nearer the ideal Antiseptic than any preparation now before the Medical World.

Send for New Formula Book and General Reports, establishing its value externally in Surgery, Obstetrics, Gynecology, Leucorrhœa, Gonorrhœa, and all Mucous Membrane Catarrhs; internally in Typhoid and other Fevers, Zymotic Diseases. Diphtheria, Scarlet Fever, Dyspepsia, Dysentery, Diarrhœa, all forms of Cholera, etc., and as a general Prophylactic.

THE BEST

—ANTI-LITHIC—

For the Uric Acid Diathesis.

LITHIATED HYDRANGEA

LAMBERT

PHARMACAL COMPANY.

ST. LOUIS.

FORMULA.—Each fluid drachm of "Lithiated Hydrangea" represents thirty grs. of Fresh Hydrangea, and three grs. of Chemically Pure Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is invariably of definite and uniform therapeutic strength, and hence can be depended upon in clinical practice.

KIDNEY-ALTERATIVE AND ANTI-LITHIC, RELIABLE, UNIFORM, AND DEFINITE.

The solution and elimination of an excess of uric acid and urates is best attained by an intelligent combination of certain forms of Lithia and a Kidney Alterative.

The ascertained value of Hydrangea in Calculous Complaints and Abnormal Conditions of the Kidneys through the earlier reports of Drs. Atlee, Horsley, Monkur, Butler, and others, and the well known utility of Lithia in the diseases of the uric acid diathesis, at once justified the therapeutic claims for Lambert's Lithiated Hydrangea when first announced to the Medical Profession, and it is now regarded by Physicians generally as the best and most soothing Kidney Alterative and Anti-lithic Agent yet known in the treatment of Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia, Albuminuria, and Vesical Irritations generally.

ON THE PATHOLOGY OF SURGICAL INFECTION, AND THE VALUE OF ANTISEPSIS.

BY A. H. P. LEUF, M. D.,

Pathologist to St. Mary's Hospital and to the Hospital for Nervous and Mental Disease, Brooklyn, N. Y.

(*Concluded.*)

To return for a moment to the question of predisposition and immunity. I know a young physician who had never been vaccinated, who had never had variola, and who was exposed for periods of days at a time to a small-pox atmosphere because of his attendance on such cases in a small-pox hospital. He even then did not get this disease. His was a case of decided immunity from this affection. There are many more. Others escape the contagium because of vaccination. Many succumb to it in spite of vaccination. Some are even vaccinated at short intervals of a few months, almost always successfully, and not only become infected with variola, but die with it. These latter are cases of predisposition. Again, given a case of scarlatina, diphtheria, rubeola, or any other acknowledged contagious disease, and given ten people, all in apparently the same condition, who never had any sickness, and one will get the disease to which he has been exposed and die, another will get it and not die, still another will get it so as to be barely perceptible, and another will escape without the slightest disagreeable experience. The remainder will distribute themselves among those mentioned. Here we have once more an illustration of immunity and of predisposition. How much depends upon the contagium, so-called, we have not always the means of judging. A strange fact in this connection is that physicians are, as a class, constantly being exposed to contagious and infectious diseases, and without protection, not even always in fair health, and how comparatively few are the instances where any of them are affected. Surely, as a class, they cannot be said to have a peculiar immunity *altogether* due to constant exposure, thus becoming accustomed to the poisons, for the exposure at the beginning is immediate and abundant, not gradual and slight. The fact is that contagium, as a rule, may be said to be of not much consequence without predisposition, and that predisposition without contagium is more to be feared as tending to the development of the disease to which the patient is predisposed than is the contagium without the predisposition.

The question now arises, what is the value of antisepticism?

When Lister introduced his dressing and gave his reasons, it was not long before he was rewarded with general credence of his views. He recalled the surgeons of the day to the care in handling and dressing wounds that had been in vogue with so much success not a great while before. He taught them to take care in operations; not to roughly handle wounded or injured tissues; to be slow and sure, rather than quick and uncertain; scrupulous cleanliness; rest, both local and general, as nearly absolute as it could be attained; and the stimulation of the wounded tissues with solutions and other preparations having the avowed object of destroying or intercepting micro-organisms, which he believed to be the special pathogenic cause of the vari-

ous symptoms often complicating, or preventing recovery from operations and injuries.* He was right in treatment, and therefore successful. That Listerism has made accessible to the surgeon's knife almost any part of our bodies, cannot for an instant be denied. How it did so admits of two interpretations, if we choose to particularize. Surgeons operating by his methods were very successful. They were stimulated by these successes to new undertakings that previously no one dared attempt. The same kind of blind fanaticism, though milder in degree, that pervaded Europe during the Crusades, the Reformation, and the mental epidemics portrayed by Ecker, also dominated the surgeons of the whole world, and antiseptics were their charm that insured final success, as was the cross that of the Crusaders.†

Lister gave the impetus that brought about these grand results, and for this merits and has received undying fame. The essentials of the methods he reinstated will probably and with good cause always prevail, but not so his theory of germs and their effects. The antiseptic rage has done incalculable good, but also a great deal of harm. Its advent was timely, else it would never have spread. Its practice with the idea of killing micro-organisms is on the wane. Its former advocates are undergoing a mental reversion. The reaction is approaching, and all should guard against its reaching the opposite extreme.

Now, what are the disadvantages of antiseptic ism?

The spray is abolished because its objections were too evident to long escape attention. The routine antiseptic vaginal douche is meeting a similar and equally deserved fate. Constant douching of a wound during an operation will also soon have to give way to a more rational and beneficial method. Pathologists and microscopists carefully preserve microscopical material from contact with water, because of its disorganizing effect upon the tissues. It ruins them for microscopical investigation. The effect of water is observed on the fingers if long immersed, giving rise to the so-called washerwoman's finger. It loses tonicity. It debilitates and enervates. The hot water immersion treatment of wounds does good by toning down the excessive inflammatory process; so do all hot moist applications, as poultices for instance, but if too long continued, they give rise to a sodden condition of the wound, and make matters worse instead of better. Carbolic acid solutions have the same effect, but in a shorter time, also benumbing the terminal nerve-filaments in the wound and the surgeon's fingers, whose tactile sensibility it is of prime importance to preserve at its best. More laparotomy cases have, in all probability, died of carbolic acid peritonitis than any of us suppose or would like to admit. I would in this connection formulate another rule—one that requires no further comment.

A local traumatic peritonitis has no tendency to spread unless it is preceded by the extension of some irritant matter from the original site of inflammation, and then the inflammatory process will follow this cause and only become general if preceded by it.

Lister's dressing and its derivatives prevent the inspection of the wound at will, and therefore are objectionable, because the surgeon should be able to inspect the wounded parts readily, and without disturbing the patient. A wound hermetically sealed, especially before glazing is completed, is objectionable in that it may give rise to bad symptoms in a feeble patient, and be followed by disastrous results, because of pent-up secretions. It is also objectionable because of the impossibility of an early detection of recurring or secondary hemorrhage. These objections have a practical side, and the dangers expressed have repeatedly happened. All the objec-

*How hard it is for the bacteriologist to prove that the good effects of antiseptics are due to germ-killing properties, may be seen from the fact that it is extremely difficult, if not impossible, to separate this germicidal property of antiseptics from their stimulating power, or to get a liquid that originally does not combine both.

† While the advance made by surgery during the last two decades, or more, is to be almost wholly ascribed to Lister's innovation, it must not be inferred that success crowned every effort because of the new way. Surgeons were taught better practical surgery entirely aside from antisepsis, and to this better surgery will eventually be ascribed the success of the more recent operators, instead of to germicidal fluids and powders because of such properties. The favorable comparison between the results attained from the practical application of the new surgery, as compared with the old, led to the performance of untried operations; these succeeding, led on to others, until, like a rolling ball of snow, slightly broken records of success accumulated so as to form the enormous, bold, and complex surgery of to-day. The misinterpretation at the beginning, as to the real cause of the improved results, the bacterial theory, grew in the same, or even greater, ratio. This sole idea of germs took possession of every unguarded professional mind, to which it has adhered, and where it has developed to the stupendous proportions of to-day. The investigations of certain bacteriologists, as for instance Pasteur and Klebs and Koch of Europe, and Salmon of this country, while justifying many inferences and establishing many minor and very few major facts, are largely the cause of the present exaggerated estimation of the germ theory in its application to surgery. The men who least understand the value of the facts and seeming facts now established in this field of research, are the ones who overburden the literature on the subject, and compel a forced postponement of a mature judgment on the results of original work in this department. Unfortunately, very few surgeons are pathologists of the practical kind, and *vice versa*. The same may be said with as much truth of surgeons being bacteriologists, and the contrary. But how seldom, if ever, do we see combined in one man the practical pathologist, the surgeon, and the bacteriologist? Sad, but too true, is the fact that in most instances each man has to theorize in two of these departments while he practices the other. This is one of those instances where science would be greatly benefited by the adoption of the co-operative plan.

tions to antisepticism contained in this paper have been demonstrated more than once in this city. So much is this so that it is useless to specify cases.

In brief, the principal points that it is the object of this paper to impress are as follows:

1. There are essentially but two kinds of union—primary and secondary.

2. All living tissues have common and special powers of reaction.

3. The common reactions are those of mere vitality, and the special reactions are the result of the performance of duties not necessary to life.

4. It is by their common reaction that cells overcome disturbances.

5. Repair in all structures is essentially the same, and only the manifestations are different.

6. Connection and support is the special duty of the connective tissue cell, and it is its sole and special duty to repair all breaches of continuity, and it does this without the aid of other cells.

7. Of all structures involved in the inflammatory process, the lower tissues, embraced by the term connective tissue group, undergo additional growth and development, while the higher tissues, embracing all that do not belong to the preceding group, become atrophied or are destroyed.

8. The repair of an open wound may be divided into three stages, extending in regular order up to the glazing of the surface, the formation of granulations and pus, and the end of repair.

9. There is transudation of blood, plasma, and serum, until glazing is complete, and of pus from the time granulations are formed until the end of repair.

10. There is no transudation from the wound from the time glazing is completed till granulations and pus are formed, but the wound's surface is protected with a coagulated albuminous layer.

11. So long as there is transudation from a wound there is no danger of absorption by that wound.

12. The possibility of absorption during the intermediate state just mentioned may be called an open question.

13. I do not believe absorption takes place, as a rule, even at this stage, if the albuminous envelope, the glazing, is perfect.

14. This intermediate stage lasts three or four days.

15. Admitting that absorption is possible at this time, and that antiseptics should be employed, they would only be indicated for three or four days.

16. Sealed dressings to remain so for weeks are not required for antiseptic purposes, and do good almost entirely by insuring greater rest to the injured part.

17. I believe that primary union is prevented principally by local and constitutional causes, and not alone by pathogenic micro-organisms.

18. Anæsthesia retards glazing, and indirectly prevents primary union because of the premature coaptation of the surfaces of the wound.

19. A local traumatic peritonitis has no tendency to spread unless it is preceded by the extension of some irritant matter from the original site of inflammation, and then the inflammatory process will follow this cause and only become general if preceded by it.

20. Surgical infection is a term too carelessly employed, and in most instances a misnomer.

21. Most often the symptoms ascribed to surgical infection are due to reactions of the whole system and of the wound against new conditions and irritations.

22. These reactions depend upon the predisposition of the patient, altered environment, and other defective conditions of life, for their characteristic manifestations.

23. The causes of most so-called infectious disorders are intrinsic and not extrinsic.

24. The absence of predisposition may here be said to constitute immunity.

25. Predisposition may be hereditary or acquired.

26. It may be gradually or quickly acquired.

27. It is not always evident, nor always possible of detection.

28. Hyperpyrexia is as normal in some pathological conditions as is the standard in health.

29. Excessive reaction is followed by temperature elevation.

30. Various affections have thermic elevations peculiar and normal to themselves.

31. If germs have any causative relation to surgical complications, they are impotent on a wound's surface unless the patient is predisposed.

32. Hyperpyrexia is produced by long-continued excessive action of any organ of the body or part of the body.

33. Local irritations, if long continued, if sufficiently strong, or if affecting a sufficiently sensitive structure, also cause a rise of body heat, and this whether or not the irritation is appreciated by the mind, although its recognition by the brain increases the effect.

34. Those tissues which have the richest nerve supply and densest consistence, as a rule, give rise to the most marked constitutional disturbances when congested or inflamed.

35. The more perfect, absolute, and continuous the rest of an injured part, the more favorable are the conditions of repair and the greater certainty is there of complete, rapid, and satisfactory recovery.

36. Conjoined with this, the most nourishing and most easily assimilable food, sustaining medication, with good hygiene and agreeable environments, constitute the best treatment of surgical cases.

37. Antisepsis is the prevention of contact between open tissues and living disease germs.

38. In a question of this kind, one negative experience, if without error, is logically as effective a refutation of a theory as are thousands.

39. One such negative experience has occurred in our midst in Dr. Jewett's case of diphtheritic cast of the vagina, and this is by no means a lone instance, as there are many others equally as conclusive.

40. Antisepticism, as above defined, is demonstrated to be a fallacy, and therefore can have no rational existence.

41. As good results are obtained by careful surgeons who do not employ antiseptics as is obtained by those who do.

42. I deny the causative relation of most so-called pathogenic microbes, because they are the results or concomitants, and not the cause of the diseases with which they are identified.

43. Lawson Tait, without the use of antiseptics, has exceeded all preceding records of success.

44. The greater success in the treatment of private patients, or patients in special hospitals over those in general hospitals, is not due to superior antiseptic facilities, but principally to greater attention on the part of the surgeon, healthier and pleasanter environments, and a superior and constantly appropriate diet.

45. Practical antisepticism, or Listerism, has its advantages and its disadvantages.

46. It does good by having revived and improved upon well recognized and highly valued older methods.

47. It has unconsciously furnished a means of overcoming the local tonicity of wounds, and it did so at a most opportune time.

48. This is accomplished by the stimulating effect upon the tissues of the so-called antiseptic preparations in moderate strength and for a limited time.

49. It has done good by instigating daring surgery, and leading to the achievement of the most brilliant, undreamt-of, and hoped-for results.

50. It is seductive, and causes men to adopt and follow it, who would be neither clean, gentle, nor careful without it.

51. Listerism may be designated a "God-send" to patients who have to put themselves under the surgical care of a large proportion of our fellow-practitioners, both in the city and country.

52. This is so because it controls them as religion controls the masses.

53. It has done harm by instituting new and pernicious methods, often at the expense of those that were older and beneficial.

54. It has poisoned many patients.

55. It has killed many other patients by increasing inflammatory action, especially of the peritoneum.

56. Its almost indiscriminate advocacy of sealed dressings is, and has in innumerable instances proven to be a source of interference with proper healing, and even an element of danger in preventing the early detection of deviations from the normal process of repair.

57. It also delays the recognition of recurring and secondary hemorrhage.

58. Its good is done under a cloak of irrationality, because its good effects are claimed to be due to the killing or inhibition of germs, whereas its benefits are wholly and unqualifiedly due to the rigid enforcement of the best surgical principles, fully recognized before the advent of the fallacy of antisepticism.

THE SOURCE OF THE URATES, AND THE PROPER MEANS OF THEIR REMOVAL WHEN IN EXCESS.

BY T. C. SMITH, M. D.,

Of Aurora, Indiana.

The terms urate and lithate are synonymous, but the former being more frequently used, will be employed in this brief discussion. "Urate is a generic name for salts, formed by the combination of uric or lithic acid with different bases." (Dunglison.) The urate of soda is the salt commonly the most found, perhaps, in urinary concretions, though of course we know other urinary salts enter into their make-up.

The source of the urates will not require a long discussion. Physiology teaches, and daily observation bears out, the fact that uric

acid, urea and urates are "found within the body by the metamorphosis of nitrogenous organic substances." They are "most abundant under the use of animal food, and diminished by a vegetable diet, and are reduced to a minimum during complete abstinence" (Dalton), though not disappearing altogether. Thus it is at once seen that the diet has much to do with the quantity of the urates found in the urine of our patients. The amount of tissue waste that goes on in the body is also another factor that determines the quantity. This latter factor is greatly influenced by rest, exercise, mental labor or worry.

"The most important fact known with regard to the origin of urea"—and of the urates—"is, that it is not formed in the kidneys, but pre-exists in the blood in small proportion, and is drained away from the circulating fluid during its passage through the renal vessels. * * * * It has not been found, however, in the solid tissues in sufficient quantity to indicate the immediate source of its production. It is either formed in the blood itself, by the transformation of some previous nitrogenous combination, or it is absorbed by the blood too rapidly to be detected as an ingredient of the solid tissues." (Dalton.) Such is the language of one of our best physiologists, used about ten years ago.

Holding in our minds the undisputed fact that urea and all its salts result from tissue waste in the body, or from the nitrogenous food ingested, we have a practical point from which to start in ascertaining their primary origin in the system.

If a nitrogenous diet increases the urates in the urine, and a vegetable diet causes, or is followed by, their diminution, then we may know for all practical purposes that organic nitrogenous food is related in some way to their production, and more especially to their excess.

If we look to the proteid compounds we will find that their free use has a decided influence over the quantity of urates in the urine. The proteids are not affected by being passed through the saliva in mastication. Gastric juice dissolves them. Upon these proteids pepsin and the gastric juice produce decided effects.

"Before digestion, an albuminoid is termed a 'proteid,' the digested proteids are termed 'peptones.' As peptones, albuminoids readily pass through the walls of the digestive canal into the blood, the change is caused by adding a molecule of water." (Fothergill.) The fat of our foods is also absorbed by the lacteal glands, after being reduced to an emulsion by the action of bile and of the pancreatic juice.

We may thus see that the peptones and the fats are thrown into the circulation, to be carried, by some means, to a higher state of preparation for tissue building as the system may demand. That these cannot be assimilated by the tissues of the body, in the state in which they are absorbed, will be readily admitted. They must be carried a step higher in the process. Where then can they be further prepared? Does the blood prepare them for such appropriation? Do the tissues themselves work the needed change? Do the nerves effect it? I trow not.

There is one great, active, industrious, much-abused gland upon which the weight of this further preparation falls almost entirely, *i. e.*, the liver. The liver is, indeed, a very important organ in the digestive process, and the term "liver digestion" is as appropriate as that of "gastric digestion." All, or quite all, of the nutrient material that the absorbents take up must needs pass through this great digestive gland, and be prepared for use or for assimilation by the tissues, and in the rapidity of the circulation and the vast blood supply of the liver, much of the nutrient material will pass through that organ and be subjected to its action many times in the period required for the complete preparation of proteids and fats for tissue building in repairing the waste natural to the system.

In the process of liver digestion, the urea and its salts have their origin, and this seems to be their source. From here they enter the circulation, from which they are filtered by the renal organs. The kidneys do not secrete these, they simply filter them out of the blood.

The liver, like the stomach, can do a normal amount of work well, and can for a time do excessive work and remain quite normal in condition. But like the stomach, when pressed long and hard by an excess of work, especially by the too free ingestion of nitrogenous compounds, it is compelled to pass much of the nutrient material on into the blood only half prepared for assimilation. From this there soon results an excess of the urates in the renal discharge. This leads me to say that under such a condition of the digestive and assimilative process, the appearance of an excess of urates in the urine stands as a clinical evidence of an overworked liver for the time being at least.

Such an overworked condition may result from the ingestion of an excess of nitrogen-

ous food, or from the partial failure of stomach and intestinal digestion, which thus throws double work on the liver. In either case the liver is not able to perform all the work required of it. As a result, part of the nutrient material submitted to its action is but partially acted upon, and it becomes waste material in the blood, which soon acts as a poison to the system. This brings on what is often called a bilious attack, a storm of sick headache, a neuralgia if complicated with malaria, a rheumatic or gouty attack. Often, however, it stops short of this, producing simply a feeling of heaviness of body, mental hebetude, and crossness of temper.

As to the hepatic origin of these salts, let another speak. Mr. Foster says (Fothergill on Indigestion and Biliousness, p. 57): "Uric acid . . . like urea is a normal constituent of the urine, and like urea has been found in the blood and in the liver and spleen. By oxidation a molecule of uric acid can be split up into two molecules of urea, and a molecule of mesoxalic acid. It may, therefore, be spoken of as a less oxidized form of a proteid metabolite than urea; but there is no evidence whatever to show that the former is a necessary antecedent of the latter; on the contrary, all the facts known go to show that the appearance of uric acid is the result of metabolism slightly diverging from that leading to urea." To this statement Fothergill adds: "It must then be regarded as the product of perverted metabolism in the liver. Prout held uric acid to have another source than urea, to be formed largely from gelatinous forms of our albuminoid food, while urea was held to be derived from ordinary albuminoid matters. This view was soon abandoned, and it was thought that uric acid was a normal product, viz., a sort of nitrogenized waste preceding urea and converted into urea by further oxidation, or by a splitting up into urea and oxalic acid. Now we regard it as a product of perverted metabolism in the liver. The appearance of lithates in abundance in the urine about the time when the liver is actively engaged in the digestive process, renders it highly probable that certain peptones, instead of undergoing further elaboration are turned aside and broken up prematurely into lithic acid and lithates. These lithates do not represent tissue waste, for they have never been tissue." That is, they have at such a time been carried to elimination before having been thoroughly elaborated to a condition fit for tissue building. Thus an excess of water may appear in the urine from an overtaxed liver. Such an overtax may result from ingesting excessively of nitrogenous foods or from imperfect gastric digestion. In either case the metabolism of the proteids is not perfectly performed, and the process of elaboration falls short of completion, thus leaving the urea and urates to be cast into the circulation in a half-prepared state, only to be eliminated by the renal organs, As Fothergill by way of illustration says: "They stand in the same relation to the tissues that a stillborn child bears to an estate that it would have inherited had it been born viable. So the material which forms the uric acid might have been tissue under more favorable circumstances"—that is, if the "liver digestion" had been carried a step further in the elaborative process.

Dr. Murchison, a high authority, in his Croonian Lectures before the Royal College of Physicians, said: "I need not remind an audience such as that which I have the honor to address, that deposits in the urine of lithic acids or lithates, are not due to any morbid condition of the kidneys; what I wish to insist on is, that the frequent occurrence of these deposits in the urine ought always to be regarded as a sign of functional derangement of the liver, arising from causes temporary and sometimes more or less permanent."

In this decided expression by an able authority, there is no uncertain sound. Fothergill endorses this opinion, and further adds: "These deposits in the urine, then, are significant of disordered fuctions in the liver. They belong to indigestion proper."

Heretofore they have been held as signs of deranged renal functions, and the pathology was referred to the kidneys. Gravel was a kidney disease, etc. Now we know we must look farther for the cause of lithates in the urine, and of renal and vesical concretions. We may then fairly know that the source of the urates is imperfect "liver digestion" when too much nitrogenous food is ingested, or when there is gastric dyspepsia that causes too much work to be thrown on the liver, and also that the lithates result from and normally represent the tissue waste of the body.

How to get rid of their excess when present, is a question of practical importance to us, for we meet with patients almost daily, who have made themselves sick by pleasing their palates at the expense of their digestive powers. It is astonishing how many ills this form of indiscretion will originate.

Under the old idea that lithic salts in the urine indicated renal disease, it was common

to give the alkaline potassa salts. For present relief, this was good practice, because of the affinity of the potassa salts for the uric acid; thus it dissolved the urates out of the blood and gave prompt relief. Yet this practice was based on a mistaken pathology.

It is well to remove the excess of urates, but to prevent a reaccumulation we should cut off all excess of animal food, and reduce the amylaceous articles of diet to the real needs of the system. This done, the excess of lithates soon disappears.

If we find a case—as we will now and then—where there does not seem to be an excess of proteids taken, where digestion is good, and yet the lithates are in excess, the urine with an ammoniacal odor, etc., I know of nothing better than the free use of hydrochloric acid abundantly diluted and sweetened to the taste.

To say that this matter of excess of the urates in the renal discharge is a small affair in a practical sense, is to take a perverted or very limited view of its importance. Such an excess of the urates indicates the fact that there is floating in the blood-current much material that is really dead, decomposing matter that acts as animal poison to the whole system. If the urea and urates, as we have tried to show, result from a failure on the part of the liver to carry its digestive process up to full elaboration of all the organic nitrogenous ingesta submitted to its action, after it passes from the stomach and intestines, then these salts represent so much animal tissue that must of necessity become decomposed in the blood-current, and is thus constituted a deadly poison to the physical economy, unless it is promptly eliminated. Whether this excess of the urates results from a redundance of food taken, or from a too rapid waste of the tissues of the body, matters not as to its poisonous effects, though it does matter as to the prognosis of the case, the latter condition being the most serious.

These retained urates will poison the whole brain and nerve centres, so as to constitute true uremia and death. I well remember a hale, hearty, fleshy young man, of 22 years, who, without known cause, beyond free cramming of animal food, with much of a rich amylaceous quality, and a common "bad cold," was suddenly attacked with convulsions and furious pain in the head. His bowels were freely purged, head was kept cool, chloroform was resorted to for controlling the convulsions, the bromides freely used, and venesection was practiced. The urine was analyzed, inspected, found to be scant in quantity; a few drops of nitric acid would render it at once almost solid, thus showing the urates to be in great excess in the urine and in the blood. This patient died comatose in about thirty-six hours. Call it meningitis, cerebritis, cerebral congestion, or whatever you like; but I fully believe if we could have cleared him of the uremic poisons floating in his blood, by securing free diuresis, free sweating, etc., we could have prevented his death.

The same poison floating in the blood current will give rise to furious storms of sick headache, neuralgia, so-called biliousness, any of which are, under such conditions, promptly relieved by the free eliminative, systemic processes, or remedies. Hence nature sets up free eneuresis, catharsis, or emesis. At once the subject is made better. Hence also the profession have learned to promptly secure this elimination by one of nature's outlets. For this reason, the old practice of venesection, cholagogues, and emetics rendered prompt relief, and were generally practiced.

The biliary and renal concretions have their origin in the same source. When these effete elements become more abundant, then it is impossible for the bile or urine to keep them in solution, then deposits occur in the bile or urine, and concretions are formed. After awhile the patient has a furious attack of hepatic or nephritic colic. If the former, the concretion is carried off per rectum. If the latter, it is left in the bladder to constitute a case of vesical calculus, unless the patient is fortunate enough to pass it away per urethra, or the urine be rendered acid enough to dissolve it. To prevent all this trouble and painful affliction, or often death, the best plan is, if possible, to regulate the diet as above indicated. If the concretions are already formed, or if the salts are thick in the urine, then we should properly regulate the diet and use free eliminating agents, as potas. bicarb., sulphate of soda, epsom salts, colchicum, etc., etc. If this condition results from the too rapid retrograde metamorphosis of the tissues of the system, as it is liable to do in the overworked, the feeble, the pregnant, and the aged, then the use of the mineral acids with proper digestive agents will best remedy the pathological condition present. In either case the patient should keep the bowels fairly soluble, use but little animal food, and drink very abundantly of pure soft water. It is an excellent practice to flood the system with water in this class of cases. Water is one of our very best systemic renovators if we will flood the tissues

with it, and among the best mineral springs in the world will be found the cistern of good pure water at our own doors. Thousands of patients who are benefited at watering-places receive their improved health more from flooding the system with water, thus washing effete material out of the tissues, than from any real potency of the waters they so freely use at such places. The free use of pure cistern water will accomplish this as well as any in the country, but will not require the exhibition of as many silks, satins, trunks, etc.

Medical Societies.

CHICAGO MEDICAL SOCIETY.

(*Continued from page* 207.)

Dr. D. T. Nelson in opening the discussion said: "Mr. President, I am glad to have heard the paper, and think it is a most valuable one. The cautions that it gives are certainly those that all of us should remember, to wit: the length of the instrument used compared with the length of the uterus, the slow and gradual dilatation of the uterus before using the inflexible stem, and removing it on the occurrence of bad symptoms. In recent years I have not been in the habit of using the stem pessary as much as my friend Dr. Jackson, but I think that with his present instructions, I shall try it again. Not that I have not tried gradual dilatation, and the gradual, slow, careful straightening of the uterus, but I have not by this particular means caused the pessary to be retained as constantly as he has. The vulcanite pessary, and the various other forms, including the Wright's or Chambers's modification, I have used, and with many of the difficulties the doctor has narrated. But with his modification it seems to me very likely we can use them with better success. The irritation produced by them has been a great drawback, and in recent years it has been my habit rather to use the form of pessary recommended by one of our members, Dr. W. H. Byford, the slippery elm bougie. It produces a gradual dilatation of the uterus, and often produces remarkable results in the treatment of the flexions, and I have had no bad results from its use. One point that the doctor did not emphasize sufficiently, is that the instrument should not be retained long if it produces pain, but it should be removed and the patient put to bed. I should have preferred to have him give directions for the patient to remove the instrument if the pain continued for a long time, for if it does the instrument ought to be removed; and if he should happen to be out of the city and the patient should be unwilling for any one else to see her, serious disease might commence before he returned and removed the instrument. For this reason it is, and always has been, my plan to have the instrument so arranged, by a string or something of that sort, that the patient can remove it herself. We should remember that the instrument should be less than the uterus by a third of an inch; that the uterus is to be put into its proper shape, in a splint, as it were, and then expected to grow right—that it is not cured when it is straightened—if it has been displaced for a considerable time there has been an atrophy of the uterine tissue on one side, and it may take weeks, or perhaps months, to alter the nutrition of the different parts of the organ, and until that change has taken place it is not likely that the patient is permanently cured, unless pregnancy has taken place, and altered the nutrition of the parts. As to pelvic inflammation, the author has been more fortunate than most of us in the use of stem instruments. One point I wish to add, viz., that when there is any possibility of gonorrhœal poison lurking in the genital passages of the female, greater care should be taken in the use of such instruments, or operative procedure of any sort, for that matter. I feel, when there is reason to suspect that this poison has once been implanted, that I hardly dare to introduce sound, pessary, or other instrument in the interior of the uterus, and believe that such an instrument should be used with the greatest caution in these cases."

Dr. E. C. Dudley said: "Mr. President: The marvelous freedom from dangerous inflammation following the treatment of uterine flexure by forcible dilatation and by the application of the intra-uterine stem, furnishes a striking illustration of the fact that the human uterus will sometimes endure an immense amount of abuse. My own preference is generally for the former method, as advocated by Goodell, Ellinger, and others, My experience has only tended to confirm me in the impression that forcible dilatation is reasonably satisfactory in its results, and that the results are reasonably permanent. I would seldom advocate the use of intra-uterine stem pessaries for retroflexion unless the flexure were of the so-called congenital variety, and therefore associated with atrophy of the uterus, a condition which is very rare. The essayist has, perhaps for reasons

of brevity, omitted to make the distinction between physiological and pathological anteflexion. This distinction within a few years has been quite clearly defined by Schultze, Fritsche, and others, and their teachings are now recognized as correct by many of the leading gynecologists throughout the world. In the light of their investigations the old diagram of Kolrausch, which for more than twenty years has generally formed the basis for the illustrations of the normal position of the uterus, is now quite generally discarded. The uterus has no absolutely fixed position, but it has a certain normal range of movements. The angle between the body and the cervix may vary according to the varying quantity of material in the rectum and bladder, from zero to at least 45°; Fritsche says 90°, and his observation is possibly within the physiological limits. When the bladder is full the uterus becomes straight and the angle of flexure disappears. When empty the angle may measure from 45° to 90°, and yet not be pathological. It is moreover probable that a flexure of much less than 45° when the bladder is empty, should be considered pathological. Furthermore, anteflexion, even within the defined limits, is always pathological if there be immobility at the angle of flexure; indeed, a displacement exists whenever the organ is restrained from its normal movements. In a word, anteflexion is pathological if the mobility at the angle of flexure be increased or decreased beyond the physiological limits, or absent. Want of a clear understanding of these simple facts has led to the invention of innumerable pessaries for straightening the anteflexed uterus, and they have been persistently employed, to the detriment of the patient, in cases of perfectly physiological anteflexion. Suppose a case: The uterus is shown by digital examination to be so low in the pelvis that when the bladder is empty its entire anterior wall is easily touched. The physiological flexure, which may be from 45° to 90°, is then perfectly apparent to the examining finger—the symptoms of vesical irritation are attributed to the flexure, and an anteflexion pessary is accordingly introduced, which produces pressure upon the anterior wall of the uterus. The symptoms disappear, and the conclusion is erroneously formed that the relief was dependent upon the straightening of the uterus, when in reality the pessary has, perhaps, produced no such effect, but has merely lifted the uterus to its health level, and thereby relieved the symptoms, which were due not to flexure but to descent. The same manner of treatment has often been followed by relief from similar symptoms attributed to anteversion, when in reality the pessary, by lifting the cervix to a higher level, has exaggerated rather than reduced the anteversion. For this reason all vaginal pessaries especially designed for anterior displacements are in no respect superior to the ordinary Hodge pessary; indeed, they are objectionable, because in overcoming the descent they press upon the uterine wall and thereby cause irritation of the organ. Anteflexion is only a symptom which may result from any one of a variety of widely different causes, such as adhesions, uterine fibroid, parametritis posterior, or failure of the puerile uterus to develop at puberty. It would indeed be irrational to attempt the relief of a symptom due to such diverse causes by any single plan of treatment. The essayist would not attempt to do this, but he has neglected to specify the particular flexures for the relief of which he deems the stem applicable. Inasmuch as many of these flexures are dependent upon uterine or peri-uterine inflammation, and inasmuch as there is reason to conclude that dysmenorrhœa and other evils are more the result of the inflammatory state than of the flexure itself, I would advise that the stem be reserved for cases which are not relieved after the inflammation has been removed by safer methods. Such a plan would certainly restrict the use of the stem to a very small number of cases, because the symptoms for which it is to be employed would so often disappear upon the cure of the inflammation. It is indeed probable that the dysmenorrhœa for which the author has employed the intra-uterine stem may depend rather upon some faulty nutrition, or upon some disease of the uterus independent of the flexure, and that the stem therefore gives relief by some change which it produces in the nutrition of the organ. If this be true, it would then follow that anteflexion *per se* really furnishes no positive indication either in itself or in its results, but that the same treatment would be equally effective under similar conditions without the co-existing flexure. Congenital anteflexion of the puerile uterus is undoubtedly a condition for which the stem may be considered one of the legitimate means of treatment. Sterility, whether associated with pathological flexure or not, has been successfully treated by the stem. Winckel says that the presence of the instrument may give a better development to the menstrual decidua, and thereby make a better bed for the ovum. One objection to the stem, strongly urged by Schultze, is

that by its use the physiological flexure is overcome, and it therefore may be said to produce rather than to relieve displacement. But we should not permit theoretical considerations to bias our judgment in face of the author's carefully observed results. His contribution is certainly a valuable one, and shows that the instrument, at least in careful hands, is less dangerous than is ordinarily supposed. The author's freedom from inflammatory results is doubtless due to his judicious preparation of each case by means of the olive-tipped bougie. Undoubtedly the observations of Dr. Jackson and others must be considered as placing the intra-uterine stem among the useful and approved resources in the treatment of these troublesome cases, but even at the risk of prolixity I again protest against the indiscriminate treatment of purely physiological anteflexion by any means soever."

Dr. H. P. Merriman said: "I have very little to add to what has been said. The use of the various methods that have been proposed seem to me to aim at one given end, to change the nutrition of the uterus. Forcible dilatation does that to a certain extent; it is temporary, however, in its action. Incision produces an alterative effect, and accomplishes its purposes. It does not succeed a great many times, neither does the temporary action of dilatation. The use of the stem pessary, on the other hand, succeeds because it is keeping up a continuous pressure upon the parts. Now, I am decidedly in favor of this treatment by stem pessary; it strikes me that it is the only rational method of treating these flexions, which are pathological. After the cause of a flexion has been removed, that is, the inflammation of the uterus, or the pressure of a tumor, or pressure of heavy clothing, or whatsoever causes it, the uterus does not always return to its natural state, and then we need to introduce some method for restoring it to its normal condition, and I do not know any more rational method than this one. This paper strikes me as a very valuable one. The valuable part of this treatment seems to me not to be so much in the use of this stiff stem, as the earlier treatment by the flexible stem, where, by continuous pressure upon the parts, we are able to accomplish the same effect as passing a sound in chronic cases of gleet, producing a healthy action in a diseased organ and thus producing absorption of a pathological exudate. It strikes me that the doctor recognizes this condition, for often before using the stiff Chambers' stem when he has been using these bougies, in a great many instances he has found the treatment has nearly cured the disease, and if it had been continued longer I believe a cure would have been effected. The intra-uterine stem by continuous pressure induces an alterative action of the tissues, the absorption of exudates, and gradual return to the normal condition of the uterus, and a natural tendency toward a straightening of the uterine canal as the uterus becomes healthy."

Dr. Sarah H. Stevenson said: "I have listened to the paper with a great deal of interest, and also to the discussion. My methods are different; I have used the stem pessary a great deal in former years, but for the past two years I have discarded it entirely, as some of the results were unfortunate, although I think I have never had any serious results from the use of the stem. I now use, and have for the past two years, the galvanic current entirely, and it is applicable to all cases, especially in those in which the stenosis is so great as not to admit the passage of the bougie. I have never found a case in which I could not use this method with satisfactory results."

Dr. H. T. Byford said: "I quite agree with Dr. Dudley in his trite but very true remark, 'It is wonderful what an amount of abuse the uterus will stand,' and I congratulate Dr. Jackson that he has discarded incision and dilatation in treating flexions. I also congratulate him upon his good success. I believe the mortality from this treatment—the treatment by the intra-uterine stem—has been estimated to be from ½ to 1 per cent. by those who have investigated heretofore. Whether it is so now, I do not know. The present per cent. of inflammation of the cellular tissue varies from 2 to 5 per cent., as nearly as I can determine. There are an immense number of cases in which the stem caused inflammation which have never been published. It seems to me that in considering this subject the reason for this treatment should be made more apparent. There are some who use it as a splint or merely to straighten the uterus; others use it as a stimulant on account of its continuous pressure. There is no doubt it stimulates and temporarily straightens the uterus, but it is well known that in time, in a large proportion of these cases, the uterus again becomes flexed. The question arises, should we straighten the uterus? As Drs. Dudley and Schultze have said certain flexions are supposed to be physiological (which I don't believe), the uterus is supported in the neighborhood of the internal os, which may be said to have a fixed place in the pelvis. The elasticity of

the tissue will allow that part of the uterus to be pressed in nearly all directions, but it will come back. The fundus may bend forward or backward and remain in such position for some time, and the uterus still be in a normal position. During youth the child who sits too much, has a curved spine, etc., having a uterus pretty firmly fixed at the cervix, will often have the uterus pressed upon by the abdominal contents in the wrong direction. The normal resistance of the uterus to flexure will be gradually overcome (the uterus may even become atrophied), and a flexion results which, when slight, may be called a physiological flexion, and may exist without causing trouble; but it is pathological. The elasticity which the uterus of normally firm structure displays during the filling up and emptying of the rectum and bladder is hardly worthy of the name of flexure. Any considerable permanent flexure occurring in this way must be the result of want of firmness in the structure of the uterus. If we are going to use a supporter, we should use it when the flexure is forming, not after it has been produced. If we will use such treatment as will remove the improper pressure upon the uterus, viz., by straightening up the spine, using exercise, etc., etc., a stem will be seldom necessary, because whatever flexion has already been produced will usually not cause unpleasant symptoms. If it has gone to the degree of producing atrophy of the uterus, we may need to use a stem passary, but as a stimulant to the uterine tissue rather than a straightener of this organ. I have seen uteri bent almost like a horseshoe become impregnated and return almost to their former degree of flexion. The intra-uterine stem, in view of its slight action as a support and powerful action as a stimulant, and its notoriously bad record, should be the last resort. The frequency with which Winckel uses the stem is now about once in 218 cases, while formerly he used it about once in 50, and he is using it less all the time. In my experience and the experience of a great many others, if we cure the acute or subacute inflammation of the uterus and then apply stimulating measures, we nearly always accomplish the cure of the flexion by safer means. There are, of course, a few cases left in which the use of the uterine stem may be justifiable, but I think they are exceedingly rare. If those present, following Winckel, use them only once in 218 times, but few of us will live long enough to do a great deal of harm."

Dr. T. D. Fitch said: "Mr. President: I think a paper so commendatory of a measure as this, will perhaps lead many members of the profession to adopt it without proper precautions and without realizing the dangers which attend the use of the intra-uterine stem. I believe it is a very dangerous instrument to use. I am an advocate, as you all know, of pessaries, but I do think the intra-uterine stem a dangerous instrument, and that in less careful hands than Dr. Jackson's serious results will often follow. My own experience in the use of it has been limited, for the reason that I became alarmed from the bad reports of cases by Dr. Chambers himself, the inventor of this bifurcated instrument which Dr. Jackson has exhibited. If the same precautions are used that are advised by Dr. Jackson, I think as a rule it might be entirely harmless—no, I should hardly be able to say entirely harmless, or entirely free from danger—but I think the precautions which he has adopted are very ingenious, and would in the majority of cases prevent serious results from the intra-uterine stem. His use of the bougies preceding the use of the inelastic stem, accustoming the uterine mucous membrane, or the uterus itself, to the presence of a foreign body within its cavity, is very ingenious, and a thing I never should have thought of myself. Although I have tried these pessaries occasionally, my great difficulty is to keep them in the uterus; I might open them in any direction I pleased, spread the blades as widely as I pleased, and they would slip out—they caused so much uterine contraction that they would be expelled from the uterine cavity into the vagina, and I have always been disappointed in the results from their use. For several years while I was in active practice I had adopted the treatment of Peasley for flexion and stenosis, whether caused by exudation or spasmodic contraction of the os internum, that is by the use of his uterotome dividing the stricture at the internal os, and then gradually dilating the canal until I could introduce a No. 12 or 14 sound through the os internum. This was introduced every second day from one week to two weeks until it ceased to be followed by pain, and by hemorrhage after its introduction, showing that the os internum had been thoroughly dilated and the incision had healed sufficiently so that no blood followed the use of the sound. After the sound was introduced I used a large glycerine tampon for the purpose of depletion and relief from irritation and to support the uterus: if it was an inversion, it would hold the fundus up so as to assist in relieving the flexion to a certain

extent at least, and preventing the occurrence of inflammation. I have treated a great many cases in this way and with entire satisfaction, and never had a case of acute inflammation of any kind occur as the result. I believe, however, that a majority of cases of flexion are attended with versions more or less. I don't believe that flexions occur so frequently as is generally supposed, unaccompanied with version; the uterus is tipped over more or less in connection with the flexion, and in connection with the treatment which I have suggested I have always corrected the version, and used the ordinary support or pessary to keep the uterus in its proper place, thereby relieving any contraction or pressure which would keep up the flexion. I think the paper an admirable one, and the Doctor's precautions in the use of the instrument he has advised commendable."

Dr. H. C. Feeder said: "I would like to ask for information. In the report of these sixty cases of inversion and retroversion it has not been stated how many were accompanied by prolapsus, or what was the cause of flexion; whether in married women getting up too soon after confinement, or whether from acute inflammation. The paper does not go into the facts and state whether the uterus is lightened and thereby goes back of itself to a normal position, nor does it inform us if this could be assisted by giving medicine internally. Much depends upon the state of the patients at the time of treatment, whether they are in a healthy condition, or whether they have some specific blood disease in which medicine would assist in the treatment; and if the medicine has an alterative effect, how much benefit is received from the medicine and how much from the pessary."

Dr. Jackson said in concluding the discussion: "Mr. President, I feel that I ought to express my thanks for the courtesy with which this paper has been received. It is only a thirteen-minute paper, and there are a great many things in the domain of medicine that are not in it, and a great many questions might be asked on subjects growing out of and connected with it, which I could not answer if I were disposed to. The intention of the paper is simply to demonstrate the efficacy of a single remedy in correcting a single deformity. Questions as to whether the uterus was prolapsed, whether the patients had taken anti-bilious pills, or had cachexia, really do not enter into the consideration of the subject. I supposed that was perfectly plain from the fact that no mention was made of anything beyond the mere condition of deformity. I am very glad so many excellent ideas have been added to it. The suggestion of Dr. Nelson as to the patient being able to withdraw the pessary is excellent, and is never omitted. I never introduce a pessary that I do not attach to it a silken cord by means of which the patient can withdraw it in case of necessity. As a rule, every patient should be able to withdraw any instrument placed in the genital passages; the regular attendant may not be at hand when needed, there may be an aversion on the part of the patient to calling in another physician, and she should have the proper means at her disposal. The remarks of Dr. Dudley as regards the distinction that should be made between pathological and physiological conditions resulting in flexion, are quite proper, and I agree with him fully. We all know that the conditions preceding and accompanying these bent conditions of the uterus are very various; and in many cases no stem, incisions, or other means will have a beneficial effect, although they may for a time cause the uterus to be straight. But the mere straightening is not always the main element of cure. When the uterus has been chronically flexed there will be a thinning of the side towards the angle, showing local failure of nutrition, either as cause or effect of the bending. Straightening, therefore, is one element of cure in a uterus where there is insufficient nutrition, and I do not believe that any other means exclusive of this cures flexion. But it must not only be straightened, but its circulation must be fully restored, otherwise the organ will resume its bent condition. We cannot put a splint on the outside of the uterus, and the intra-uterine stem affords a means by which the uterus may be kept straight enough to allow of circulation on each side. The method of treating flexions by forcible and extensive dilatation does more than dilate. It straightens, also. A bend may be just as acute in a large tube as in a small one, and mere stretching will not suffice, and its results usually not be permanent. Gradual dilatation is much more promising, and next to the method by the stem I would prefer it. I have only treated cases of flexion in which dysmenorrhœa was present, a symptom that interferes with the patient's health, and the dysmenorrhœa was usually cured or relieved. I do not think this such wonderful success; only about two-thirds of the cases were cured, some were simply improved, and in some I do not know the result. Yet I think there is no other method that will do quite as well.

The suggestions made in the discussion accounting for the safety and success of the treatment are, I think, correctly attributed to the preliminary measures—the slowness of the straightening and the promptness with which any tendency to harm could be met. The object was to accustom the uterus to its tenant, so that by and by it would accommodate a larger one, and in this way the uterus has been made to receive and tolerate the presence of an inflexible instrument. In one case a Chambers' stem was retained twenty months, and I think if the patient had not returned and told me she was wearing it, it would be there yet. It produced no unfavorable symptoms."

Dr. A. R. Small reported

A Case of Pistol-shot Wound.

May 2, 1886, he was called to see F. R., aged 23, who, a few minutes previously, had received a shot from a No. 32 pistol. Patient was suffering from shock, difficult breathing, and excessive pain in the left leg below the knee. The ball had struck the right eighth rib about two inches external to the costal cartilage. Sensation was lost in the right leg below the knee. Motion was not impaired in the right leg, though the sensation was lost below the knee. The left leg was hyperæsthetic below the knee, and motion slightly impaired. A drainage-tube was inserted about two inches into the wound, and the wound dressed antiseptically. The patient complained of no pain except in left leg below the knee, where the pain was excessive. Morphia was given hypodermically in sufficient doses to control the pain. Nothing was allowed the patient the first twelve hours but ice, and occasionally water. About 10 p. m. there was evidence of internal hemorrhage, and the patient seemed to be sinking. Milk was then given in small quantities frequently. The morning of the 3d he had rallied somewhat.

The urine was drawn by the catheter every eight hours, and contained blood. Respiration was normal after the first two hours.

On the afternoon of the 3d patient became delirious, and continued so, with occasional lucid intervals, until death, which occurred at 4:20 p. m. of May 4.

Autopsy five hours after death. Rigor mortis well marked. Unfortunately, through a misunderstanding, the undertaker had preceded us, and injected his preserving fluid, so that we were unable to determine exactly the amount of blood in the right pleural cavity. It must have been quite large, however, as the right lung was entirely collapsed. The ball made a clean round hole through the centre of the eighth rib on the right side, about two inches from the costal cartilage, passed through the lower side of the right pleural cavity, without injuring the lung, passed through the diaphragm, right lobe of the liver, and superior portion of right kidney, and through the inter-vertebral foramen between the eleventh and twelfth dorsal vertebræ on the right side of the spine, and lodged against the posterior surface of the body of the eleventh dorsal vertebra, just within the spinal cord, where it was so firmly imbedded that it could not be returned without disarticulating the spine, which, for sufficient reasons, we did not do.

Though we found the right lung collapsed, respiration had been normal except the first two hours after the injury.

Dr. Alfred S. Houghton read a paper on

The Danger in Specialism.

He said that specialties greatly increased medical knowledge and skill, and had secured for many much reputation. Hence young practitioners grasp any excuse for becoming specialists. But man is not a machine, but a complicated organism, and disease is complex, one organ sympathizing with another; hence it is necessary to examine every portion of the body and treat all organs affected. Hence there is danger in a specialist limiting his sphere of action and usefulness to an unnecessary degree. Another danger is that specialists are apt to become egotistic, and give rise to utterances which they will afterwards regret.

Treatment of Post-Partum Hemorrhage.

No time is to be lost when the life-blood of the parturient woman is rushing with feverish haste from her rapidly exhausting body. It is an emergency for which the physician should be always prepared. If one remedy fails, he must quickly try another, for every moment is precious. We note that Dr. M. S. McMahan (*Denver Med. Times* for August), on finding the surface of the patient pale, the extremities cold, with profuse hemorrhage, at once injects hypodermically from ten to fifteen minims of Magendie's solution of sulphate of morphine. This will invariably, and within a few minutes, produce a flushed surface, warm extremities, and a stopped or much diminished flow. He adopts no other means—no styptics, no cold compresses, and no foolish "plugging." This method he claims to have practiced with success for fifteen years.

Illustrations of Exceptional Symptoms and Examples of Rare Forms of Disease.

Mr. Jonathan Hutchinson thus writes in the *Brit. Med. Jour.*, July 24th:

Coffee-Stain Patches on One Shin, Distinctly Lupoid in Character and Probably Syphilitic: on the Other Shin Similar Patches, but not Yellow.

A gentleman, whom I had treated for syphilis many years ago, consulted me, in February, 1885, for an ulcer on his tongue, which he supposed to be a reminder of his disease. I found, far back, a small epitheliomatous ulcer, which had apparently not been preceded by syphilitic changes. I inquired as to any other symptoms, and he assured me that he had never suffered anything since my treatment; but, after a little thought, added, "I have some yellow patches on my legs." I found, on the front of his left shin a group of yellow spots, covering a space half as large as the palm, and placed very near to each other. They were very conspicuous by their color, but scarcely raised, and only scaly in the slightest possible degree. On careful inspection with a lens, it was quite certain that the disease spread serpiginously, and left thin scars where it receded. It was, therefore, clearly a lupous process, and probably it was consequent on his syphilis, though located by bruising of the part. On the opposite leg he had a similar group of scars, leaving patches; but, curiously enough, they were not in the least yellow, but rather livid and dusky. Those on the left shin were almost a bright yellow, brighter than the common coffee-stain.

I use the term coffee-stain as applicable to certain yellow patches which are often seen on the legs. All observers must be familiar with them, but I am not aware that they have ever been described. Patients who have had syphilis often show them, and seek advice in consequence, but they may be seen also in those who have never had that disease. They differ in some cases in tint from lemon-yellow to deep brown. In some instances, mostly syphilitic, they leave exceedingly thin scars.

Case of Eczema-Erysipelas: Recurrent Attacks on Face.

Certainly one of the most important cases, as illustrating the relationships of this affection, which I have ever seen, was that of a gentleman, who was brought to me in 1885 by Dr. Macpherson, of Mildmay Park. Mr. D. G. P. was a collector, aged 42, a nervous man, liable to dyspepsia; but, by dint of his out-of-door occupations, maintaining usually fair health. Ten years ago he had a sharp attack of erysipelas of the face and head, caused, as he thought, by going through the Thames Subway when in a perspiration. After this, nothing occurred for six years, when he sprained an ankle, used arnica, and had an attack of erysipelas of his leg. A year later, he sprained the other ankle, avoided arnica, and yet had erysipelas. For this attack he was treated by steel, and "the steel caused eczema." He had a troublesome attack of eczema of the scrotum and thighs, which lasted for months, and which, indeed, had scarcely even yet quite left the groins and popliteal spaces. This persistence must, I think, be held to be conclusive as to the eczema kinship of this dermatitis, as the transitoriness of the others allied them with erysipelas. We now come to another phase of his ailments. He took to bicycling, and used to perspire profusely in his rides. In October, 1883, after a ride in a sharp wind, he had an attack of swelling of the face (erysipelas), which laid him up for a fortnight; and, ever since then, he had had attacks every six months or so. On one occasion, leaving a hot dinner-room, and going across the street in an east wind, brought it on. Several times, riding in a hansom cab had done it, and now and then, he thought, stomach disturbance from taking wine, etc., was the exciting cause. The attacks were ushered in by "a rushing to the head," and "feeling of fulness and flushing." "Then it seizes my eyes, and the lids are swollen up till I cannot see out." Dr. Macpherson, who had attended him through four or five attacks, told me there was not usually much redness, but chiefly great œdema.

The temperature was never materially increased. The eruption never showed any tendency to spread over the scalp, and usually began to subside after a few days, leaving the skin feeling stiff, and covered with branny desquamation. No vesicles had

ever been observed. The attacks always laid the patient up for a fortnight or three weeks, and of late his susceptibility had been such that he had scarcely been to business for two months.

As regards treatment, the prophylactic power of arsenic seemed to have been fairly tried. He had taken it for eighteen months, and the attacks had of late increased, both in severity and frequency. Formerly, the attacks had occurred in spring and autumn, and this was the first time that one had happened during winter.

Injury to Lower Epiphysis of Humerus: State of the Parts Twenty Months Afterwards.

A little girl, aged 4, a daughter of the Reverend G. P., of the Chinese Mission, was brought to me twenty months after her accident. It was not known precisely of what kind her violence had been, since it had occurred under the charge of a nurse-girl, who only admitted that she had fallen. The elbow was bruised and swollen for some time. She was treated by plaster-of-paris case, and subsequently by a hinged splint. When brought to me the elbow could not be bent quite to a right angle, nor could it be straightened. It admitted, however, of being flexed within a limited extent. Pronation and supination were quite free. The arm was strong, and the child could use it for almost anything, but could not get it to its mouth. It appeared probable that the injury had been complicated. The head of the radius projected strongly, as if almost, though not quite, free from the external condyle. The finger could be placed in the outer two-thirds of the cup of the radius; still it certainly had not wholly left the condyle. The distance between the ulna and radius was much increased, and, no doubt, the orbicular ligament was completely torn. The inner condyle was lost; the inner side of the ulna being on the same plane, or nearly so, as the inner edge of the humerus. Then there was some thickening on the front of the humerus in this position, making it seem possible that the epicondyle had been broken off and displaced forwards. The thickening in front of the lower part of the humerus was, however, not nearly so great as is usual in separation of the whole lower epiphysis. Under an anæsthetic, I bent the elbow up to an angle of 45°, and made it very nearly straight. I advised that we should trust to time and to systematic and vigorous movements of the joint, and have little doubt that, in the course of a few years, its use will be almost perfect.

In the case of a boy, aged 10, whom I saw at the College of Surgeons (1885), it was very remarkable how rapidly full freedom of all motion had been restored. It was, I think, only nine weeks since the accident, yet there was not the slightest swelling, and he could flex and extend almost perfectly, and pronation and supination were equally free. The external condyle, together with the trochlea for the radius, was visibly displaced, and was very conspicuous. Some who examined it thought that it was still movable. The internal condyle was almost, if not quite, in due relation with the olecranon; but there was some thickening of the humerus, and the olecranon did not appear to project so much as usual. My impression was that the end of the shaft was displaced a little backwards, but I had not an opportunity for forming a deliberate opinion. Every one agreed that there had been fracture and displacement of the external condyle, but, as to other details, there was much difference of views. The wonder was that there could be such displacement, with yet perfect motion.

Node on Tibia, Without Syphilis, and Without Pain.

Mr. Weller, of Wanstead, sent to me in October, 1883, a case of osseous node on the tibia, which appeared to be identical with the splint of horses. Nothing whatever as to specific antecedents could be made out, and the lump was absolutely painless. It had never given its possessor any annoyance; it had been present several years, but, unless he got it knocked, he should not, he said, have known it was there. The patient was a tall slender-boned man, and the node, which was as big as the vertical half of a small egg, was very hard. The patient, a Mr. S., aged 39, was engaged as a clerk in the docks, and was liable to have his shins knocked occasionally, but he did not remember any special accident. The node had been so conspicuous two years ago, that a surgeon, to whom he showed it, suggested that he must have had his leg broken; it was, however, still bigger now.

Morphœa, Taking the Arrangement of Zoster on Chest and Arm: Twenty Years' Duration: Recent Single Patch on Back.

Miss C. A., aged 36, consulted me on March 19, 1885, for an eruption which she had had for twenty years. She well remembered its beginning, she said, on the inner side of the right forearm, during her last

year at school. It prevented her from going without sleeves, and it also, she thought, was attended by muscular weakness, and spoiled her piano-playing. After it had been some years on the forearm, other patches appeared on the side of the right half of the chest, between the spine and the mamma, and above the latter. I found in the regions mentioned, large brown stains, and groups of stains, placed exactly like those of herpes, in a sloping line downwards and forwards on the chest, and another long group of stains down the inner side of the upper arm and forearm. The breast on that side was not so full as the other, and there was a little appearance of wasting in the ulnar muscles of the forearm. I could not, however, appreciate any definite wasting in the muscles of the hand supplied by the ulnar nerve. In the middle of some of the brown stains there was a white area. The affected skin was a little harsh and rough, but there was not now any material induration. None of these patches were, Miss A. believed, less than ten or fifteen years old. A new patch had, however, formed within the last eight months on her back. This was an oval patch, as big as a crown-piece, thick, white, and brawny in its middle, gradually fading off, and surrounded, at its extreme periphery, by a faint violet zone. This was most characteristic of the early stage of morphœa. It itched a little. Miss A. was in good health, but had a very feeble circulation. Her hands were a little puffy, and everywhere of a deep dull brick-red color, or almost livid.

The case illustrates, almost better than any other that I ever saw, the affinity of morphœa with herpes zoster. Probably, several of the intercostal nerves were affected; and, not only the intercosto-humeral, but some twigs of the internal cutaneous, possibly some of the ulnar. Neither herpes zoster nor morphœa usually keeps with exactitude to the known distribution of named nerves. It is interesting to note that, after so long an interval as twenty years, a fresh patch had formed on the back. The same happened in the case of M. This new patch was not on the same side of the trunk, but it was over the middle line to so small an extent, that it must be allowed to be possible that an erratic twig from the right supplied it. The conditions presented by the patches on the chest and arm suggested that they had all come out together—all were in the same advanced stage of retrogression. Miss A. was, however, confident in her statement, that those on the breast came five years after those on the arm.

It is very exceptional for morphœa to occur in the same person more than once. When it does so, the interval is almost always a long one, that is, several years. The second outbreak is usually on a very limited scale. I never saw a severe or extensive second attack, but I have seen three or four in which small patches appeared, as just said, after long intervals. As a rule, we may assure our patients that the deformities produced by the original outbreak will be the sum and end of their troubles, and that no recurrence is likely to happen. In the above case, three outbreaks, with long intervals, would appear to have occurred. In this feature of very exceptional recurrence we have another point in which morphœa and herpes have points in common.

Chloride of Sodium in Bright's Disease.

This is certainly a very simple remedy, yet Dr. Allard Memminger, of Charleston, S. C., highly lauds it in the *New York Med. Jour.*, July 31. He has only tried it, so far, in four cases, but his observations are of value, because it alone was used, to the exclusion of all other drugs. At first he orders ten-grain doses of the chloride, contained in gelatin capsules, three times a day, and, if the state of the case allows, by preference one hour after or before meals. He generally reverses each day the order of giving; thus, if one day the capsules are given before meals, the next they are prescribed after. If the patient complains of no nausea, he allows him to keep up; but at the slightest intimation of a sick stomach, he orders him immediately to assume the recumbent posture, and there remain for an hour or so, after which this temporary ill-feeling always subsides. The second day of treatment he increases the dose to two capsules three times a day, and every other day he increases by one capsule until the patient is taking five capsules three times a day. About this time the good effects of the treatment will be apparent, not only from the improved subjective and objective symptoms of the patient, but from the improved condition of his urine. Albumin will, of course, at this period be found still in abundance, that is, if the case is at all a grave one; even here, however, if you institute a gravimetric examination, you will find a decided improvement, not so much in the absolute as in the relative decrease in albumin.

At this juncture he orders the chloride to be diminished in quantity, and he has so far found that, after the system has thus been

brought fully under its influence, it requires but two capsules, three times a day, to keep up the desired effect. If at this stage of the case there is any decided nausea or disinclination to take the medicine, he stops the same, and during the interval gives one or two alterative pills, after which he proceeds again to a resumption of the chloride. Should albumin again increase in the urine, urea and chlorides diminishing, he immediately resorts to large doses, thus bringing the patient once more under the influence of the chloride, after which he again reduces.

The effects of this treatment are most marked. Headache, œdema, low spirits, general weakness, and anæmia, give way to just a reverse order of things, and the patient, who a few days before was most gloomy and desponding, is now full of life and hope.

Thus has it appeared to him in each of his four cases, and, if he has been led to express views that to many appear extreme, it is because his convictions are based upon clinical observations which, up to this time, he has never had the pleasure of recording with any other form of treatment. He would, therefore, urge a thorough trial of this therapeutical agent by the profession, on the following grounds:

1. It is harmless if properly administered.

2. Its effects are comparatively uniform, provided it is given for a sufficient time. That he has so far used it only in chronic cases of no long standing does not in his opinion militate against its beneficial effects; for, even should it not be found a cure for Bright's disease, may it not become an important article in our medical armamentarium—indeed, if only an ameliorator of man's sufferings and a prolonger of his life?

3. It may be employed as an adjunct to all recognized methods of treatment without detriment to the patient.

Thus, then, he asks the practitioner, teacher, and scholar, does not an array of such facts, coupled with the well-known physiological action of chloride of sodium, demand from each and every one of them a fair and honest trial in this most formidable of diseases?

The Treatment of Orchitis and Epididymitis.

Dr. Frederick W. Lowndes thus writes in the *Lancet*, July 24:

There is a sufficient diversity of opinion as to the best treatment of orchitis and epididymitis, the result of acute gonorrhœa, to induce me to give our experiences at the Liverpool Lock Hospital. When I first became surgeon, eleven years ago, I found that the practice adopted in all these cases was that which had been suggested by Mr. Furneaux Jordan in 1869, viz., by painting the affected testicle with a strong solution of nitrate of silver (two drachms to one ounce), at the same time enforcing strict rest in bed and supporting the inflamed organ upon a small pillow, so as to prevent it from hanging down. It had been adopted for some years previously by Messrs. Worthington and McCheane, who were the surgeons to the hospital at the time when Mr. Jordan suggested this mode of treatment; and also by Mr. Chauncy Puzey, who succeeded Mr. Worthington, during the two years of his surgeoncy. I have invariably pursued the same treatment now for eleven years, and so has my colleague, Dr. Armand Bernard, who succeeded Mr. McCheane in 1882, and has thus had four years' experience of the treatment.

At my request, the resident superintendent of the hospital, Mr. Serjeant, has given me the following statistics of all the cases of orchitis and epididymitis combined from June 1, 1875, to June 1, 1886, an interval of eleven years. The numbers are as follows:

Years.	Number.
1875 to 1876	32
1876 to 1877	15
1877 to 1878	22
1878 to 1879	28
1879 to 1880	30
1880 to 1881	16
1881 to 1882	31
1882 to 1883	28
1883 to 1884	24
1884 to 1885	18
1885 to 1886	25
Total	269

All these were patients admitted into the hospital; we have no out-patients.

I have always found the treatment I have mentioned most successful. The acute pain, often amounting to agony, is soon subdued, and in the majority of cases the testicle returns to its normal size in the course of a few days. Sometimes a second painting is necessary, but this suffices. In private practice I have always used the same application. When patients can be induced to take absolute rest in bed, the result is equally successful as in the hospital. When, however, patients are compelled to follow their usual occupations, the recovery must obviously be slower, as it is impossible by any suspensory bandages or by handkerchiefs, however skilfully applied, to ensure such

perfect rest for the testicle as when the patient is lying in bed. I have heard it argued that rest in bed is sufficient of itself to effect a cure, but a very few cases so treated with spirit lotion as an application has convinced me that it is not so. The immediate effects of the nitrate in allaying the pain are most marked, though for obvious reasons the nitrate must act more powerfully upon the testicle while in a state of quiescence than when constantly moved, however slightly.

Mr. Jordan has informed me that he still pursues the same treatment, having every reason to be satisfied with it. It seems to me to be only just to him to give this very satisfactory proof of the value of the treatment which he originally suggested.

A Piece of Percussion Cap, After Lying Quietly in an Eye for more than Ten Years, Sets up an Irritation which Necessitates Enucleation.

Dr. S. L. Ledbetter, thus writes in the *Alabama M. and S. Jour.* for August:

I was called to see Mr. McL———, four miles out from Springville. I had been previously consulted by his friends in reference to his condition, and had expressed an opinion as to the probability of an enucleation being necessary, so went prepared. The family physician and two other local physicians went out with me.

We found the patient in a closely-curtained room. He was very much emaciated and nervous; said he had no appetite, and was very much depressed; had been suffering almost constantly for the past five or six weeks with his eye. Nothing gave him any relief but morphia. He stated that about eleven years before, while shooting, a piece of gun-cap struck him on the eye; that his eye pained him a good deal for a week or two; but as soon as the immediate effects of the injury passed away, his eye was all right and caused him no uneasiness, save the impairment to vision. So he went along until the preceding fall, when he began to suffer from neuralgic attacks in that eye, which were very severe, and usually laid him up for a week or ten days each time. The attack from which he was then suffering had lasted longer and had given him more pain than former ones, and had so reduced him that he felt, unless something was done for his relief, he could not stand it much longer.

Upon examination I found the eye very sensitive to light, with considerable injection of conjunctiva and sub-conjunctival tissue, but could not make a very careful examination, as the eye was so very irritable. (I had not begun the use of cocaine then.)

There was also a line of corneal opacity passing from the inner margin of the cornea toward the pupil, a lenticular opacity and a posterior synechia, showing that the body had passed into the inner structure of the eye. There had been no sympathetic trouble in the other eye, but on account of the distance and inconvenience of getting to the patient, together with the amount of suffering the patient had endured, with very little prospect of recovery, I advised enucleation. The patient and his attending physician both agreed to the operation, which was done under ether.

Upon examination after the enucleation, it was found that the lenticular opacity was confined to the outer margin of the lens where the body passed, tearing off a portion of the lens, and setting up an irritation which resulted in synechia. After a very careful search the body was found lodged in the ciliary processes to the outer side of the eye. It was a small fragment of metal, no larger than a mustard seed.

The patient made a good recovery, and has had no further trouble. His general health improved very rapidly, and in a short while he was able to attend to his business as usual.

Lithotomy in Children.

The following statistics by Werewkin (*Centralblatt für Chirurgie Medicale, No.* 8,) are of much interest, as showing how suitable an operation lithotomy is for children:

"From July, 1876, to January, 1884, there were admitted to the Children's Hospital 221 cases of stone in the bladder; here are the statistics, with the ages of the patients:

						Per Cent.
From	1	to	2	years	17	(7.69)
"	2	"	3	"	44	(19.92)
"	3	"	4	"	46	(20.82)
"	4	"	5	"	47	(21.22)
"	5	"	6	"	21	(9.50)
"	6	"	7	"	9	(4.07)
"	7	"	8	"	10	(4.52)
"	8	"	9	"	11	(4.99)
"	9	"	10	"	10	(4.52)
"	10	"	11	"	8	(3.62)
"	11	"	12	"	7	(3.16)
"	12	"	13	"	8	(3.62)
"	13	"	14	"	2	(0.90)
"	14	"	15	"	1	(0.50)

210 of which were boys and 11 were girls. 13 only of the 221 cases were unsuited for operation. The lateral operation was done in 147 cases, the median in 16 cases, the 'high'

operation in 24 cases, by external incision of the urethra 17 cases.

"In the lateral operation on reaching the bladder the wound was enlarged by a scalpel, not the lithotome, the stone seized, and the wound washed out with an 8 per cent. solution of chloride of zinc, and then sprinkled with iodoform afterwards. A silver catheter was introduced into the bladder through the wound for drainage. The recovery usually occupied three to four weeks. The complications were few, ten failed, nine became erysipelatous, two got orchitis, and three died from accidental causes.

"Of the 135 cases which recovered, seven suffered from fistula, and two had incontinence of urine. Of the twenty-four 'high' operations seven died; in two of the cases active peritonitis occurred. Of the sixteen median operations there was one death, and one case of fistula; five cases were recut. The stones for the most number were unequally sided, round, or oval, from 1 to 3 c. in diameter, and in weight averaged about 10 grammes. The operations were carried out with antiseptic precautions, and unless the first day after the operation, there was no elevation of temperature."

The Value and Dangers of Antiseptic Methods.

Dr. A. R. Smart thus concludes a paper in the *American Lancet* for August:

In conclusion, we offer these propositions:

1. The precautions incident to the antiseptic treatment are of the greatest value independent of their connection with the germ theory, viz., drainage, cleanliness, and rest.

2. Antiseptic agents may accomplish as much by preventing decomposition in wounds, thus destroying a fertile field for the development of germs, as by the destruction of the spores themselves.

3. Antiseptic agents, especially corrosive sublimate and acid carbolic, are often used in too strong solutions, thereby inducing local irritation and rendering systemic poisoning possible.

4. Antiseptic surgery is not desirable in abdominal surgery, so far as concerns the local use of antiseptics, general antisepsis and perfect cleanliness giving the best results.

5. The use of antiseptics in obstetrical practice should be limited to abnormal labors, and when intra-uterine injections are used only the weaker solutions should be used, and they only with the greatest caution to insure their ready escape. Corrosive sublimate is to be regarded as the most dangerous of all agents thus used. In gynecological practice the same caution should be observed, several instances of salivation and death even having followed vaginal douches of corrosive sublimate.

We can but protest against the advice to leave from 90 grains upward of iodoform in either the vaginal or uterine cavities. In the routine treatment of cervical or vaginal diseases we would advise the use of milder antiseptics, especially the use of boro-glyceride.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The address of Dr. J. P. Thomas, of Pembroke, Ky., president of the Kentucky State Medical Society, has been printed in pamphlet form. The subject is "The Doctor as an Officer of the State." It is treated in a thoughtful manner.

——Dr. W. S. Whitwell, in a pamphlet before us, reports a case of successful transfusion in typhoid fever.

——M. Pasteur, and his method of treating hydrophobia, is the subject of an intelligent exposition by Dr. Thomas M. Dolan, of London, published by H. K. Lewis, 136 Gower street, London. Price, one shilling.

——In a pamphlet published by Cupples, Upham & Co., Boston, Dr. V. Y. Bowditch discusses the question of homœopathy from the homœpathist's standpoint.

——Dr. A. B. Judson, of New York city, in a reprint before us, reviews the treatment of white swelling of the knee, and gives his conclusions as to what constitutes the most efficient methods.

——Dr. Llewellyn Eliot, of Washington, reports in a reprint two unsuccessful cases of permanent drainage for ascites, the details of which should make practitioners cautious about this method.

——Dr. David Prince, of Jacksonville, Ills., has issued a second edition of his essay on Atmospheric Purification; and Dr. A. E. Prince, of the same city, sends an account of an improvement in the operation for pterygium.

——Several new medical ventures appeared on the first of July. The *Medical Missionary Record* is to be a monthly maga-

zine devoted to the interests of medical missions. Its editor and proprietor is Dr. G. D. Dowkontt, 118 East 45th street, New York, and its terms are $1.00 a year. Our own opinion on the aims of this journal may be very briefly put: that it is wise for missionaries to learn and practice medicine; and that it is unwise for medical men to do any theological teaching or talking.

BOOK NOTICES.

A Manual of Practical Therapeutics, Considered with Reference to Articles of the Materia Medica. By E. J. Waring, M. D., and D. W. Buxton, M. D. Fourth edition. 1 vol., pp. 666. P. Blakiston, Son & Co., 1886. Price, cloth, $3.00; sheep, $3.50.

Many years have elapsed since the first edition of this work appeared, and in that time great changes have taken place in the fashions of therapeutics. To meet these, and to present this important branch of medicine in its latest light, the authors have diligently revised the text of the previous editions, and present the volume now as an exponent of what is latest and soundest in therapeutical teaching.

The articles of the materia medica are arranged alphabetically throughout, and each is discussed chemically, medically, and therapeutically. Its physiological action is also touched upon, although this is considered subordinate to the strictly clinical aspect. Numerous formulæ are inserted in the text, suggesting favorable combinations of ingredients. Several very complete indexes are added to the volume, which greatly facilitate its use as a work of reference. In its present revised form, Waring's *Therapeutics* will long preserve the popularity which it has heretofore enjoyed.

Analysis of the Urine, with Special Reference to Diseases of the Genito-Urinary Organs. By K. B. Hoffmann and R. Ultzmann. Translated by T. B. Brune and H. H. Curtis. Second edition. Pp. 310. Price $2.00. New York, D. Appleton & Co., 1886.

The rapid advance which urinary analysis has made within the last three years, as well as the exhaustion of the first edition of this work, has called upon the translators to give the text a careful revision and to add a description of various tests and methods which have of late come into vogue. This they have done in a very complete and conscientious manner, rendering this treatise probably the most exhaustive one on the subject now in our language. They have also appended to the work a translation of Dr. Ultzmann's description of his saccharimeter, and a carefully-prepared index; a number of beautifully-executed photographic illustrations of crystals are also appended.

The Use of Electricity in the Removal of Superfluous Hair and the Treatment of Various Facial Blemishes. By George Henry Fox, M. D. Pp. 67.

The Modern Treatment of Ear Diseases. By Samuel Sexton, M. D. Pp. 95.

Inhalers, Inhalations, and Inhalants. By Beverly Robinson, M. D. Pp. 72.

New Medications. By Dujardin-Beaumetz, M. D. Translated by E. P. Hurd, M. D. 2 parts. Pp. 320.

The works whose titles are given above are portions of "The Physician's Leisure Library," published by George S. Davis, Detroit, Michigan. They are issued at the uniform price of 25 cents each, or a series of twelve for two dollars. The paper is good, the type clear, and the general high literary character of the selections is guaranteed by the names and standing of the writers. The subjects are those which have an immediately practical bearing, and upon which recent and trustworthy information will be welcome to the mass of readers. The volumes are placed at a price so reasonable that we cannot doubt they will meet with a sale equal to their merits and to the legitimate expectations of the publishers.

The Treatment of Hemorrhoids.

Various are the means suggested for the relief of this painful affliction. One surgeon prefers this, another that method; one patient will only submit to the ligature, while the next will not tolerate it. So it is, diversity of opinion, diversity of willingness on the part of the patient, and consequent doubt. So, Dr. Charles B. Kelsey, of New York (whom we all know to be a man of great experience), after devoting several pages to a discussion of this subject in the *Med. Record*, August 7, concludes thus:

"After all has been said, I can only add that the most satisfactory cases of hemorrhoids, of moderate or great severity, which come to my notice, are those in which the patient says at the outset, 'Cure me as you think best.' In them I use the clamp and cautery. They seldom cause a moment's uneasiness, and the result is always very gratifying."

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM OF MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

ETIOLOGY OF TYPHOID FEVER.

The bacillus of typhoid fever has long since been discovered, it has been artificially cultured, and its nature and specific properties have been investigated. Some writers still deny the existence of this pathogenic bacterium simply for the reason that they do not find it invariably present in the bodies of individuals having died with the disease, nor in the blood of patients suffering from it. But they forget that no pathogenic bacteria are always met with in the disease they cause, their presence mainly depending upon the stage of the malady. For instance, in relapsing fever the spirilli are found in the blood in numberless quantities during the febrile period, while in the interval no such bacteria are met with. In cholera the comma bacillus can easily be demonstrated in the intestinal canal of patients, recently sick with the disease, while later, when mortification has attacked the mucous membrane of the bowels another bacterium takes its place, and the specific bacillus is no longer found. Another point of importance is the seat of the pathogenic microbe; in cholera it would be useless to hunt for the bacillus in the blood, and in tuberculosis we would look in vain for its micro-organism in the brain when the lungs are alone affected.

Drs. E. Fraenkel and M. Simmonds have recently contributed an interesting article on the bacillus of typhoid fever, and published the same in the *Ctral. f. Klin. Med.*, 1886, No. 44. They obtained the following results, which well illustrates what we said above:

1. In 12 cases of typhoid fever the bacilli could be isolated and matured by pure culture of the germs taken from the spleen. In a thirteenth case, where the typhoid disease had ended and the patient had died with pulmonary gangrene, the bacillus could not be found.

2. In slices of the spleen the presence of the bacillus was demonstrated easier, if they were left for a few days under a cover-glass and with antiseptic precautions, and then hardened.

3. The blood of typhoid patients gave in six cases an absolutely negative result.

4. In the discharges from the bowels the bacilli were met with in only 3 of 7 cases.

5. Inoculation of 27 rabbits with typhoid cultures into the auricular vein was 15 times successful, from injections into the peritoneal cavity 1 of 14 rabbits died, from such into the duodenum none evinced any unfavorable result; of 20 gray mice, 14 died after intraperitoneal injection, and of 3 guinea-pigs 1.

6. Death ensued in these cases from within a few hours to at the most 3 days.

7. Animals that had not succumbed after the first injection, did also not die from repeated inoculations, with one single exception.

8. In the fatal cases swelling of the spleen, of the mesenteric glands, of those in the axillary and inguinal regions, and of Peyer's patches, was invariably met with. Almost invariably from slices of the spleen, and always from pure cultures, the same bacilli were over and over reproduced.

The bacillus of typhoid fever may serve, therefore, as a means to discover the cause of death in obscure epidemics, such as have recently occurred in small cities of our country. For this purpose bacteriological examinations should be made of the spleen of such individuals who died while still suffering from the acute stages of the disease, for after this has run its course or when complications have set in the specific bacillus can no longer been found.

FIBROID PULMONARY PHTHISIS.

Dr. A. Sokolowski has made a careful study of 40 cases of so-called fibroid lung phthisis (*Deutsch. Arch. f. Klin. Med.*, xxxvii., p. 433), *i. e.*, that form of consumption whose anatomical basis is characterized by extraordinary proliferation of the connective tissue, which generally develops either primarily or oftener secondarily after other acute diseasesof the lung or the pleura. This form is mainly characterized by its very chronic course, lasting years and decades, also by the absence of fever and by its inclination to transient standstills of the disease; later the symptoms of common phthisis set in, but possessing certain peculiarities.

From a clinical point of view, the following varieties had to be distinguished:

(*a*) The common fibroid phthisis (phthisis fibrosa simplex); and, (*b*) fibroid phthisis complicated with pulmonary emphysema (phthisis fibrosa ab emphysemate).

Regarding hereditary influences, fibroid phthisis is inherited far more rarely than common tubercular phthisis, and the malady generally develops in later age. Though the disease usually sets in after some acute lesion of the parenchyma of the lung, or of the pleura occasionally, hæmoptysis is to be looked upon as the causing element. S. believes that the fibroid phthisis differs only in so far from the common form as hereditary influence plays no part, and as the connective tissue is specially affected.

Concerning symptomatology, the patients usually look well; fever and night sweats are wanting. Cough and expectoration vary in the different stages; tubercular bacilli are always found in the sputa, but in small quantities. Dyspnœa is one of the most important signs; hæmoptysis is very constant, often habitual, and not accompanied by fever or any bad consequences. The physical signs also vary according to the stage. Morbid changes in other organs are met with but seldom, as laryngeal ulceration, or such in the intestines, or nephritis. As the course of the disease is very chronic, the prognosis quoad vitam is far more favorable than in the common phthisis.

Therapeutically, S. recommends in the first stage residence in mountainous regions, also cold douches; in the second stage with its cough and dyspnœa such residence is contraindicated, and that near the ocean recommended; also a milk or kumys cure, cod liver oil, glycerin, alcohol, and arsenic.

THE STATE BOARD OF HEALTH OF PENNSYLVANIA.

It is very gratifying when any man or body of men have labored earnestly and untiringly for the public good, to see their labors appreciated. For this and other reasons we think it well to give editorial publicity to the following remarks from the *Pittsburgh Times* of July 30. Under the editorial heading of "It Has Proved its Right to Be," this valuable paper says:

"The service rendered by the State Board of Health to the people of West Elizabeth in their affliction by the outbreak of fever, is an illustration close to home of the usefulness of that organization.

"In such cases people are likely to lose their heads, and to need above everything directions as to what they should do. They call meetings and discuss the perils, but disperse as undecided as when they assembled. The local doctors are usually busy with the sick, and have little time to give counsel as to sanitary arrangements. Besides that, they are pretty sure to differ as to the origin and nature of the pestilence, and as to the best means of suppressing it. The State Board stepping in with a system of rules concerning the closing of wells and preparation of hospital accommodations, is welcomed as a succorer, and its instructions are the means of restoring confidence and leading to intelligent treatment of the danger.

"The Board has hardly reached the end of the first year of its existence, but what it has done, as at Elizabeth, and at places still

nearer Pittsburgh, in abolishing nuisances perilous to health, is sufficient argument *for its right to be, and to be amply supported.*"

These italicised words should be well pondered, for of what use will be the most efficient Board, if it be not amply supported, both *morally and financially.*

SALT IN BRIGHT'S DISEASE.

We would call attention in an especial manner to the remarks of Dr. Memminger (page 240) on the beneficial influence of chloride of sodium in Bright's disease. This is truly a very simple remedy, and if it has any curative effect over this terrible malady we should at once establish the fact. We would strongly urge our readers to give this remedy a fair and full trial, and report the results.

Notes and Comments.

Badly Made Trusses—Large Strangulated Femoral Hernia—Successful Herniotomy and Radical Cure.

How frequently is more harm than good done by the use of a badly-made truss. Therefore, we note that Mr. Vincent Jackson, in describing some improperly made trusses, in one of our English exchanges, narrates the following case: A woman, aged 44, stated that, when 23 years of age, whilst laughing heartily, she felt something come into her right groin. By degrees, a swelling appeared, and a truss was applied; but from this period, in spite of every kind of instrumental support, the hernia gradually increased until it reached very large proportions. As a rule, a night's rest had enabled her to return the hernia; but twenty hours before Mr. Jackson saw the patient, symptoms of strangulation commenced. The hernia was seen to be very large, occupying almost the upper half of the left thigh. It felt very tense, and seemed to contain fluid, intestine, and omentum, as was verified upon the operating-table. The tumor being freely laid open, much red serum flowed away, and the huge coils of congested small intestine were reduced, although the neck of the sac was freely incised, and stretched to its utmost extent. The omentum was carefully overhauled, but, as it was much changed in appearance, being puckered, thickened, and altered in color, the whole was first secured by tying it at various points with carbolized silk, and then cutting it away. The sponge which had been placed over the intestines being removed, the neck of the sac was stitched together. Poupart's ligament and the fascia forming the outer edge of the saphenous opening were carefully approximated. As much of the sac as possible having been cut and torn away, the edges of the wound were united with sutures and drainage-tubes; and the dressings having been applied, the patient was removed to bed. The lady made an excellent recovery, and, although a light truss was directed to be worn, the cure was complete. The piece of omentum removed weighed one pound and a half.

A Case of Ununited Fracture of the Humerus, and a Method of Treatment thereof by Metal Screw-taps.

These "ununited fractures" are frequently so troublesome that we are glad to note that before the Academy of Medicine in Ireland, Mr. Henry Fitzgibbon exhibited a brace fitted with drills and screw-taps for the fixation of the resected bones, and reported a case of ununited fracture of the humerus which he had successfully operated upon by this method. Mrs. T., admitted into the City of Dublin Hospital, 13th March, 1885, with comminuted fracture of humerus which refused union, was sent to seaside until November 14th, when she was readmitted with permanent non-union. Operated upon November 26th successfully by means of screw-taps and wire suture, which were removed on the 21st day after operation. The patient was exhibited to the Academy with firm union and a useful arm on April 16th. Mr. Fitzgibbon attributed the non-union to the pressure of the comminuted fragment being displaced upwards, so as to cause pressure upon the brachial vessels, depriving the lower fragment of sufficient blood-supply.

The details of the apparatus could be secured by addressing the author, care of the *London Medical Press,* in which journal the report appears.

Ligation of the Vertebral Arteries for Epilepsy.

A great fortune and imperishable fame awaits the man who will devise any means by which a radical impression can be made on *Simon-pure* epilepsy, that is to say, on epilepsy not dependent upon syphilis. The question of ligating the vertebral arteries has been more than once broached, and it is thus summed up in the *Neurological Review* for July by Dr. J. L. Gray, of Chicago:

1. Ligation of the vertebral arteries should take its place as a recognized procedure in the treatment of certain cases of epilepsy.

2. The operation should be confined to those cases in which the exciting causes of the attacks come from some region outside the brain.

3. The arteries should be tied as high up as practicable, and the ligature should include all the fibres of the sympathetic accompanying the vessel.

4. Where the side of the brain which is first invaded by the disease can be determined, the artery of that side should be ligated.

5. Where the invasion of the disease is apparently bilateral, both vertebrals should be ligated.

6. This operation should not be done as a substitute, but as an aid to other forms of treatment for the relief or cure of epilepsy.

Puerperal Tetanus.

Dr. W. Netzel mentions in the *Hygeia* a case of puerperal tetanus. The patient was a woman of twenty-five, a primipara, who was brought to the lying-in hospital by a midwife a day and a half after labor had commenced. The fœtus was dead, and its large head locked in the pelvis. The os uteri was 5 centim. in diameter, thick, and rigid. Perforation was resorted to. The fœtus and placenta were expelled spontaneously five hours later. The cavity of the uterus was washed out with a 3 per cent. solution of carbolic acid. The temperature rose on the fourth day, and the lochia became putrid. Intra-uterine injections of a 3 per cent. solution of carbolic acid were used, and the vagina was washed out with sublimate. On the eighth day trismus and stiffness of the neck appeared. The following day there was stiffness in the shoulder and spasmodic contractions of the facial muscles, with painful spasms. The temperature was 41° C.; pulse 140. The woman died at midday. Chloral had been given, and subcutaneous injections of morphia and curare. On making a post-mortem examination an ulcer was found in the cervix reaching through the uterine walls to the peritoneum. There was parenchymatous degeneration of several organs. Dr. Netzel considered the tetanus in this case to be a symptom of general septic infection.

Cure of Basedow's Disease by Operation.

The case which Prof. Hack reports in the *Deutsche medicinische Wochenschrift*, June 24, 1886, is a strange one. A girl of 17 was suffering from Basedow's disease, with well-marked symptoms. The mucous membrane of the nose happening to be so much swollen that she had to keep her mouth almost constantly open, she came to Prof. Hack for relief. He cauterized the smaller mucous membrane on the right inferior turbinated bone, and found next day, to his astonishment, that the exophthalmos on the side operated on had almost disappeared. He operated on the other side, and anxiously awaited the result, which was also favorable, but not such a brilliant success as the first attempt. Strangely enough, the other symptoms likewise improved, and the operation on the nose seems to have cured Basedow's disease itself. Prof. Hack's explanation of the result is that the disease, in this case at least, was purely reflex, and that as soon as the irritation in the nose ceased the disease vanished. The increased action, and even the increased size of the heart, he attributes to this same reflex action; the coronary arteries might be dilated, and thus give the organ an over-plentiful supply of blood. He further upholds his reflex-theory by giving parallel cases.

Cocaine Aided by Electricity to Act as a Local Anæsthetic.

O! thou glorious drug; what virtues dost thou not possess! Truthfully, after a time, it will be easier to enumerate the virtues wanting to, than those possessed by, cocaine. It is well known that the simple application of a cocaine solution upon the sound skin has no anæsthetic effect. This may, however, be brought about, accorning to Dr. Wagner, of Vienna, by combining an electric current with the cocaine. It is known that the electric current has the property of causing the forward movement of fluids which are contained in capillary tubes—this is called the cataphoric force or effect of the electric current. If the electrodes of a battery are moistened with a solution of cocaine, it has been found that the latter is propelled into the cellular tissue, causing the skin to become anæsthetic within a few minutes, so that it may be punctured with needles or cut with knives without causing any sensation or feeling of pain. Any desired amount of skin surface may in this manner be made anæsthetic. The anæsthesia lasts ten to fifteen minutes, but may be prolonged by applying an Esmarch bandage previous to the application of cocaine. This is a most pregnant suggestion, and we would be glad to publish any experiences that our readers may have in this line.

The Menopause and Diseases of the Ear.

The influence of the menopause on diseases of the ear has been the subject of a recent paper (*Annales des Maladies de l' Oreille et du Larynx*) by Dr. Ménière, and results from 140 carefully made observations are given.

The paper is divided into two very distinct parts: First, the influence of the menopause on disease of the ear already existing. Second, the diseases of the ear caused by the influence of the menopause.

On already existing ear disease the influence of the menopause is but slight, and amongst those so influenced the author includes chronic inflammation of the external meatus, perforation of the tympanum, eczema, vegetations, and polypi. Of the middle ear he includes catarrh of the eustachian tube, chronic catarrh of the tympanum, etc. In the second group he includes furunculi of the external meatus, eczema of the external meatus, of the middle ear, myringitis, acute pain, buzzing noise, vertigo, deafness, and Ménière's disease.

The pathology of these diseases is, according to Dr. Ménière (*La France Medicale*), readily explained by the great vascularity of the organ of hearing, and its hyperæmic conditions during the menopause.

Recovery from Severe White Swelling of Knee.

Before a recent meeting of the Medico-Chirurgical Society of Edinburgh, Mr. A. G. Miller showed a case demonstrating recovery from white swelling of the knee-joint of a severe type. The patient, a boy, had been under his care twice for this affection, and on each occasion had recovered. The treatment at first was the application of Scott's dressing and elastic pressure. On the last occasion on which he returned, the joint was so far gone and the ligaments affected to such an extent that amputation was recommended, but declined. In its place the actual cautery was applied. When the slough came away excessive hemorrhage occured, and continued for about a fortnight. It turned out that the boy was a bleeder, and it was therefore fortunate that amputation had not been performed. The recovery of the joint was as perfect as anything he had ever seen, all the movements being quite restored.

Ununited Fracture of Left Patella; Lister's Operation; Recovery.

About a year ago a powerful young man entered the Perth Infirmary for fracture of left patella. He had been treated in the usual way for three weeks; but when he was examined the fragments were found 1½ or 2 inches apart. As there was not the least attempt at union, and the fracture transverse, Dr. James P. Bramwell (who reports the case in the *Edinburgh Med. Jour.*) chloroformed him, laid open the joint very freely under antiseptic precautions, refreshed the surfaces, bored the fragments vertically in three different places, brought the surfaces into excellent position, and hammered in the wires after dividing them.

From first to last there was scarcely any appreciable constitutional disturbance, and the large wound healed by first intention. From his timidity, however, in using his leg, there persisted some stiffness in the joint, which gradually gets less by persistent exercise.

Congenital Malformation of the External Ear.

Dr. T. R. Williams, of Beechtree, Pa., writes thus to the *Med. News*: "Mrs. T——, of this place, gave birth a few days ago to a female child who had a deformity of the left external ear. The cartilaginous portion was entirely wanting, and the soft parts were in a very rudimentary condition, except the tragus, or what I took to be it, which seemed to have about its usual development. The external auditory meatus was completely obliterated, not even a trace of any opening showing. Whether this condition obtains throughout the entire canal I cannot say, as I made no operation to ascertain this. The child weighed about nine pounds, and was otherwise perfectly developed. I would add that not long since I delivered a member of this same family of a child with hare-lip. I closed the fissure by an operation, using the hydrochlorate of cocaine successfully as a local anæsthetic."

Echinococcus in the Arm.

Dr. Nolte describes, in a recent number of the *Allgemeine Med. Central. Zeitung*, the case of a woman who, in April last, consulted him on account of a swelling in the inner bicipital furrow of the left arm. It has been present three years; it was small and painless, and grew steadily, but until lately did not prevent her from performing hard field labor. She took no notice of it, and did not seek medical advice until it became troublesome. When seen, it had the size and shape of a goose's egg, and felt hard and distended; there was no fluctuation or

murmur; the tumor was quite painless. At the lower part was a small opening, from which fluid escaped. The arm having been carefully cleansed, an incision was made under strict antiseptic precautions, when there escaped about fifty echinococcus-cysts, varying in size from a pea to a walnut. The wound healed soon, and recovery was complete.

Hysterectomy and Nephrectomy.

La Gazzetta degli Ospitali (July 21) reports a successful operation by Professor Calderini, of Parma, for the removal of the entire uterus. The organ had been completely prolapsed for some time, and was the seat of multiple sub-peritoneal myomata. The temperature after the operation never exceeded 37.7° C. Of six vaginal hysterectomies four were successful in the hands of Professor d'Antona, of Naples. This operator has devoted much attention to renal surgery. He prefers lumbar to abdominal nephrectomy, and thus summarizes the statistical results of the two operations up to this date. In 111 lumbar nephrectomies the percentage of mortality has been 39.93, whereas the abdominal method practiced 120 times is said to have yielded a death-rate of 50.83 per cent.

Heart Disease following Over-exertion.

J. Seitz in Zurich, Corvisart, Hope, Kreysig, Albutt, Peacock, and many others, have all maintained that heart disease is frequently due to over-exertion; but since Bouilland showed the close connection between heart disease and acute rheumatism, the over-exertion hypothesis has been pushed rather far to the background, and the object of a paper by Leyden (*Zeitschrift fur klinische Medicin*) is to restore it to its merited position. With this view he gives a short resumé of writings on the subject, pointing out the frequency of cardiac ailments among the harder worked classes and soldiers under the hardships of war. He refers particularly to Peacock, Myers, and Da Costa, and others who give both facts and opinions strongly in favor of the over-exertion theory.

Pruritus Ani.

"How will you relieve 'pruritus ani?'" is the cry of many a physician, who has been driven to his wit's end. Many means have been recommended, but few prove permanently effective. We now note from the *Moniteur Therapeutique* that M. Grellety recommends, for the simple form, frequent Sitz baths, ano-perineal douches, or bathing the parts several times daily with warm water, containing one part per hundred of boracic acid. During the night he uses a starch poultice, or an ointment of oxide of zinc and vaseline, one part to five. If these fail, he uses tents saturated with belladonna ointment, and then a five per cent. solution of cocaine introduced into the anus. The food must be simple and bland.

Vesico-Vaginal Fistula—Rupture of the Perineum and Extensive Division of the Recto-Vaginal Wall.

Mr. Vincent Jackson, of England, relates the case of an unmarried girl, aged 18, who was admitted into the hospital a month after being confined of a still-born male child at full term. She was attended by a midwife; and, after being in labor for twenty-four hours, she was seen by a medical man, who delivered her by the aid of the forceps. Her height was 4 feet 8½ inches. She was completely restored from a very wretched and uncomfortable condition by three operations. Two were required to close the large transverse vesical aperture, and one to restore the perineum and re-unite the unusually long recto-vaginal fissure.

The Treatment of Syphilitic Iritis.

This is an alarming condition that calls for prompt interference; no mere temporizing, if we wish to save the eye. Dr. S. G. Dabney tells us, in the *Am. Pract. and News*, that he at once brings the patient under the influence of the bichloride or protiodide of mercury in combination with iodide of potash. Darkness should be insisted on and tonics given, if required. The pupil should be dilated at the start (with a few drops of a four-grain solution of atropia), and this dilatation maintained until all signs of inflammation are gone. This is the basis of treatment; of course, symptoms must be managed as they arise.

Treatment of Cholera amongst the Chinese.

According to a communication of a European doctor (*Alleg. Wiener Med. Zeitung*) living in China, the municipal treatment there for cholera consists in acupuncture and cauterization, not only adopted by the mass, but also by the educated classes. Chinese physicians who have studied in Europe ascribe the best results to this treatment. The Chinese explain the beneficial results of this treatment by declaring that the poison of cholera gathers in certain points of the body, which the skilful physician discovers,

and from which he draws off the poison. The pains which are due to the cramp are unquestionably relieved by the treatment.

The Bacillus of Typhoid Fever.

Dr. George W. Lewis has been making some experiments with this individual, and he describes them in the *Buffalo M. and S. Jour.* for August. Of six mice and two rabbits inoculated with a pure culture of this organism, four of the mice and both of the rabbits died inside of nine days. The only pronounced symptom—and this was common to all exceptone rabbit—was the constant and exhausting diarrhœa. Upon examination, no marked changes were detected in the spleen or in any of the intestinal glands.

Electricity for Tinnitus Aurium.

"One man's meat is another man's poison," and the kind and amount of electricity that will cure John Smith of tinnitus aurium will not do the same for Tom Brown. So Dr. Julius Althaus very wisely tells us in the *Lancet* (July 31). He has found electricity very beneficial in this annoying complaint, but each separate case must be a study in itself, and that form of electricity and that strength used which is found to be effective in controlling the "ringing."

Hypodermic Solution of Quinine.

When it is necessary to administer quinine subcutaneously, the following formula is recommended by Dr. S. Burt, as being as little irritating as possible:

℞.	Quiniæ bisulphatis,	ʒj.
	Acidi borici,	gr. ij.
	Morphinæ sulphatis,	gr. ¼.
	Aquæ destillatæ,	℥j.

Amyl Nitrite an Antidote to Cocaine.

Dr. Shilling reports in the *Medical Chronicle* that a female patient, to whom a solution of cocaine had been administered hypodermically, became suddenly unconscious. Suspecting that this was due to a contraction of the blood vessels in the brain, he caused her to inhale the vapor of three drops of amyl nitrite, which restored her in a very short time.

New Local Anæsthetics.

Dr. Mays claims that a five to a ten per cent. solution of brucine is an efficient local anæsthetic, especially useful in relieving pruritus. The same author has shown that hypodermic injections of one to two or three grains of a solution of theine relieves the pains of neuralgia.

Correspondence.

Sleeping with Open Windows.

Eds. Med. and Surg. Reporter:—

Man is placed at the head of the animal kingdom, and why he does not enjoy the same immunity from disease that characterizes the inferior animals is, in all probability, attributable to his absence of consistency in regard to a strict observance of those habits which are indicated by his true relation to other material and immaterial matter of the laws of creation. His body is a combination of most wonderful and perfect organs, and, when subjected to precision in the observance of the laws directing and controlling healthy functions, will last a long time, endure much fatigue, and perform great labor. This is manifested in the long lives of the many men who, by careful regard for their physical health, are enabled to enjoy their three score and ten years without the pain and disorders incidental to an imprudent life and careless mode of living.

THE SUM OF HEALTH.

The laws of nature are the laws of health, and he who most closely observes such laws will have the greatest promise of a long life, freed from interruptions of the natural performance of the functions of the organs of his body. Many think they can control or direct nature as the whim of their misguided notions or passions may dictate; but it is not long before this is found to be a serious mistake. The violated laws of nature and of health soon send pain and disease as the penalty, to mark and name the acts of insubordination to the injunctions of the mandates of the principles that govern a harmonious working of the respective organs of the body. Therefore there are other suicides than those who take their lives by violence, whose suffering and premature end could be directly traceable to flagrant acts of rash imprudence in reference to an observance of those dictates of nature relative to the maintenance of a healthy condition of the body.

SLEEPING IN THE NIGHT AIR.

Man has his bed and the beast has its lair, and it is an instinctive law of the nature of the beast, when it goes to sleep, and the atmosphere is of a temperature much below that of its body, to secrete and seclude itself as much as its surroundings permit, from the benumbing influence of such cold air; and if to sleep in the night air were not injurious to the animal economy, the beast would not be instinctively led

to avoid it, for when beasts sleep in the cold night air they always place their nostrils near their sides, in order to breathe the air tempered by the warmth of their bodies; and even birds, whose lives are spent in the air, usually sleep with their bills beneath their wings, or hidden among the feathers of their breast. From these observations of the mode of sleeping of the inferior animals, we learn the relation of sleep to night air, and ascertain the great efforts which such animals make to protect their bodies and lungs against its injurious influence; but it has been reserved by superior and intelligent man to rise above the teachings of instinct, and arrogate to himself a knowledge far surpassing the sure and steady prescience of nature; and like the conceited German prince who, it is said, strutted abroad one morn and exclaimed that if he had been present on the morning of creation he could have made things better.

An individual is never known to suffer from sickness or disease caused by sleeping in a clean room from which the night air is excluded; but certainly many have been known, beyond peradventure, to contract sickness, from which they have even died, from sleeping in rooms to which the night air was freely admitted. The thorough ventilation of a bed-room in the morning, while it is being put in order, is very proper; but sleeping in it during the night with the air from without pouring into it, is both improper and undoubtedly perilous to health. It is not only the lowered temperature of the night air that is so seriously objectionable, but it is the breathing while asleep of the gaseous poisonous properties which the night air always contains in a more condensed and active form; and it is for this reason that night air is instinctively and proverbially considered prejudicial to health.

DANGER OF NIGHT AIR.

Most beasts line their lairs with dead grass, moss, or other substances, not to make them soft, but to make them warm. This instinctive act is directed by nature in obedience to the physiological fact that when the body is at rest and asleep the organs do not perform their functions with the same activity that they do when the body is in motion. Hence, the bodily temperature always sinks slightly during sleep; and if while asleep, cold air is allowed to come in contact with the body and the lungs, the result is that heat is carried off more rapidly from the sleeping person than is commensurate with health, and has the effect of diminishing the resistance of the system to those morbific influences so characteristic of night air.

The rays of the sun rarefy the air of the day, and cause a greater dilution or diffusion of the poisoned particles in the air, while at night the air becomes condensed by the cooling of the earth, and its humidity is greatly increased in comparison with the air of the day. As a consequence of this humidity of the night air, the poisonous particles which it, to a greater or less degree, always contains, become concentrated, more potently noxious, and rise to a much higher level. It is also at night that the emanations from organic decay are more perceptible; and malarial and miasmatic poisons extend with greater rapidity, and do their most deadly work. The penetrating and dangerous properties of the chill, damp air of night, can not possibly be otherwise than most injurious to the sleeper who breathes it; for while asleep he has no protection against it, and it gathers in and about him, surrounding his bed with malaria and miasm.

DELICATE PERSONS.

A person with a good constitution, and living properly, is the one best protected against the causes of disease, and will even resist with great power the potency of both local and general poisons of either a tangible or intangible form; but one with a weak or delicate constitution, attended with an improper and imprudent manner of living, is always more or less liable to the causes of disease, and is the most susceptible and early victim to those poisonous emanations which are taken into the lungs through the medium of the atmosphere, and poison the blood by their peculiarly noxious atoms; and surely this class ought to be the least desirous of occupying sleeping-rooms to which the night air has free access.

CONDITION WHILE ASLEEP.

The individual who sleeps at night near an open window is less protected than he is in the day time. On going to bed he takes off his heavy clothing to put on night-clothes which are lighter and better conductors of heat. He lies between sheets over which are usually thrown comforts and blankets, and if the covering should not be large enough to fall well down around the bed, and he be restless during his sleep, he is very apt to get the covering disarranged, and thus sleep all night with some portion of his body exposed to the night air. In this way the night air obtains a ready contact with some unprotected part of his body, lowering its

temperature, giving him cold, enfeebling his system, and rendering him more liable to the poisonous effect of those germs of insidious diseases with which night air is ever known to be freighted. Had each season a uniform temperature, the sleepers with open windows at night would fare far better; but unfortunately this is not the case. The respective seasons have variable temperatures, and a cold wave often makes in a few hours a difference in the temperature of from ten to thirty degrees. When such changes occur at night, the sleeper is generally unconscious of it; and, not having provided himself with extra bedclothing against such a contingency, often awakes chilled and painful; and should he, under such circumstances, escape serious illness, it will be the exception and not the rule. Therefore, individuals who sleep with open windows run risks which they cannot control; and while one may be benefited by the habit, at least ten are injured by it. For these unavoidable reasons, the delicate and frail should be very cautious how they let the night air in upon them while asleep, for such imprudence often forms material for death.

Even the most robust who sleep in the night air frequently awake in the morning with a husky voice, dry nostrils, pains in the limbs, and uncomfortable feelings about the chest, to tell them that they took cold during the night, and to warn them against the risk and imprudence of letting the external air in too freely into their sleeping rooms at night.

J. B. Johnson, M. D.

Washington City, D. C.

A Clever Malingerer.

Eds. Med. and Surg. Reporter:

Your correspondence of July 31st ultimo- "Caught in His Own Trap," reminds me of a case that a brother surgeon in the con, script department of the Confederate army related to me. A stout, robust-looking conscript was brought in by an officer. The surgeon put the usual question; "Upon what reason do you claim exemption?" Answer. "Piles." "Very well, we will have to examine you." "Oh yes, certainly, Doc. I know that." He very promptly placed himself in proper position for examination, and indeed, so ready and willing was he to be examined, that the surgeon felt sure it would be but a formality; but as soon as he saw the anus, the appearance of the parts, and then for the first time the man's muscular development, and every other appearance of perfect health, his confidence in the man weakened. "But how can he expect to 'fool' me in a claim of piles?" He proceeded with the examination in the usual way, and at once his finger came in contact with evidently an abnormal tumor, very large, and too hard for any pile he had ever felt. Pretty soon he got an ocular demonstration, and found he could pass his finger all round it, and that it was not attached to anything. He got hold of it with his forceps, drew it out, and said, "*Chicken gizzard*, you are exempt; but my good fellow, you must go into the army."

S. W. C.

A Caution about Croton Oil.

Eds. Med. and Surg. Reporter:

I recently was called to a patient in convulsions. When consciousness returned, I decided to give him some croton oil, as he had been very constipated. Two drops were poured on a lump of sugar, which was placed in his mouth and, I supposed, swallowed. Turning my back, I heard my patient say, "What is this?" Looking at him, I found he was holding the lump of sugar between his forefinger and thumb. I ordered him to swallow it, which he did at once, but *I neglected to wipe his fingers.* Shortly afterwards he drew his fingers across his nose and eye, and within two hours he had the most intensely inflamed eye (lasting for three days) that I ever saw; in addition to which his nose was decorated with a most beautiful blister of vigorous proportions.

Cal. E. F. J.

News and Miscellany.

American Neurological Association.

At the annual meeting of this association held at Long Branch, N. J., July 21, 22, and 23, the following papers were read:

"The Accurate Collocation of a Suture and Fissure in the Human Fœtus," by Dr. Burt G. Wilder, of Ithaca. "Importance of the Study of Cerebral Convolutions," by Dr. Charles K. Mills, of Philadelphia. "Lesion of Both Temporal Lobes, Causing almost Absolute Loss of Memory of Events, without Word-deafness or Deafness," by Dr. L. C. Gray, of Brooklyn. "Pseudo-hypertrophic Paralysis," by Dr. V. P. Gibney, of New York. "A Case of an Infant with multiple Tumors of the Cerebrum, probably of Specific Origin," by Dr. Sarah J. McNutt, of New York. "The Cause of Electrotonus and the Normal Formula of Polar Reactions," by Dr. G. Betton Massey. "Electrical Dosage," by Dr. Jacoby. "Micro-

cephalic Girl," by Dr. Amidon. "Notes on the Brain; an Additional Case of Independence of the Par-occipital Fissure," by Dr. B. G. Wilder. Dr. Mills then presented the brain of a baboon and of a negro, sent by Dr. Formad, of Philadelphia, but time was not afforded for a careful examination. "On Some Affections of the Nervous System associated with Tuberculosis," by Dr. Leonard G. Weber, of New York. "A Decerebrized Frog," by Dr. Wilder. "Pseudotabes from Arsenical Poisoning," by Dr. C. L. Dana, of New York. "The Treatment of Facial Spasm," by Dr. Wharton Sinkler, of Philadelphia. "Remarks on Epilepsy," by Dr. E. D. Fisher, of New York. "Intracerebral Hemorrhage in the Young," by Dr. Sachs, of New York. "Auctioneer's Cramp," by Dr. Zenner, of Cincinnati. "A New Portable Battery," by Dr. Jacoby. "Moral Insanity; a Plea for a More Exact Cerebral Pathology," by Dr. Jas. H. Lloyd, of Philadelphia. "A Median Section of the Head of a Murderer, Injected with Alcohol," by Dr. Wilder.

OFFICERS FOR THE ENSUING YEAR.

President—London Carter Gray, M. D., of Brooklyn, N. Y.

Vice-President—John Van Bibber, M. D., of Baltimore, Md.

Secretary and Treasurer—G. M. Hammond, M. D., of New York.

Councillors—Dr. B. Sachs, of New York; and Dr. Wharton Sinkler, of Philadelphia.

The International Medical Congress.

The *London Lancet*, the most widely read and influential medical journal in the world, speaks thus cheerfully of the International Medical Congress, in its issue of July 24th:

"Our latest information is to the effect that the arrangements for the great International Congress at Washington are progressing favorably. In the case of many of our European brethren the occasion of a visit to the United States will be an unique one in their lives. We have not yet reached that familiarity with the Atlantic which is such an attainment in our American brothers,

> Qui siccis oculis monstra natantia,
> Qui vidit mare turgidum.

Nevertheless, many on this side are anxious to return the visits so generously made from the other. And whatever the discomforts of the voyage or the severity of the *mal de mer*, we are likely to have the advantage of much brotherly assistance and advice. It may mark a new era in the treatment of sea-sickness, when so many zealous physicians and surgeons are set in competition for their own relief. Be this as it may, great preparations are being made in Washington and elsewhere, and it only remains for Europe to see that the guests are forthcoming. It is the great element in all such gatherings that they be well "furnished with guests," and we would now urge on the profession and its leaders that they will do a great service by an early decision to attend, and still more by an early intimation of it to those concerned. There are American physicians who have visited England annually for thirty or forty years, and on rare occasions perhaps more than once in the year. The late Dr. Flint, whose absence will be acutely felt at Brighton this year, and at Washington next, has come of late years to think nothing so refreshing as a run to the old home of his forefathers. Let us reciprocate the compliment on this high occasion, and make the very Atlantic the measure of our desire to cultivate international science and friendship.

Mississippi Valley Medical Association.

At the twelfth annual meeting, held in Quincy, Ill., July 13 and 14, Dr. H. M. Lane, of Carthage, Mo., read a paper on "Yellow Fever in Brazil;" Dr. Louis Bauer on "Laparotomy for Symptoms of Ileus;" Dr. A. H. Ohman-Dumesnil, of St. Louis, on "An Unusual Case of Lupus Erythematosus;" Dr. Arch. Dixon, of Henderson, Ky., on "Perineal Lacerations;" Dr. I. N. Love, of St. Louis, on "Artificial Alimentation;" and Dr. Frank R. Fry, of St. Louis, on "The Etiology of Chorea."

Dr. Dudley S. Reynolds read a paper on "Optical Defects in the Eye and Their Correction." Papers were also read by Dr. Amos Sawyer, of Hillsboro, Ill., on "The Therapeutics of Bismuth and Asclepias Tuberosa;" by Dr. L. H. Cohen, of Quincy, on "Electro-Therapeutics;" and by Dr. E. B. Montgomery on the "Therapeutics of Hot Water."

OFFICERS FOR THE ENSUING YEAR.

President.—Isaac N. Love, St. Louis, Mo.

First Vice-President.—Joseph Robbins, Quincy, Ill.

Second Vice-President.—Jacob L. Geiger, St. Joseph, Mo.

Third Vice-President.—Thos. B. Harvey, Indianapolis, Ind.

Secretary.—J. L. Gray, Chicago.

Treasurer.—A. H. Ohman-Dumesnil, St. Louis, Mo.

Assistant Secretary.—Edw. Allcorn, Houstonville, Ky.

Committee of Arrangements.—Dudley S. Reynolds, Louisville, Ky.; Louis McMurtry, Danville, Ky.; James H. Letcher, Henderson, Ky.; J. N. McCormick, Bowling Green, Ky.; L. B. Todd, Lexington, Ky.; J. Q. A. Stewart, Frankfort, Ky.; J. M. Holloway, Louisville, Ky.; J. M. Matthews, Louisville, Ky.

The next annual meeting will be held at Crab Orchard Springs, Ky., on the second Tuesday in July, 1887.

Iowa State Board of Medical Examiners.

The new Iowa State Board of Medical Examiners met recently and adopted rules for granting certificates, and a schedule of minimum requirements of medical colleges to secure recognition was adopted. A list of nearly three hundred medical schools was adopted to be recognized by the Board. Nearly one hundred colleges were refused recognition. Certificates will be refused upon failure to present a diploma from a recognized medical college, failure to submit the proper affidavits, or, upon examination, to answer correctly eighty per cent. of the interrogatories propounded. In all cases recommendation of good moral and professional standing must be given. The Board held meetings in other parts of the State, beginning at Dubuque, July 29, Mason City, Fort Dodge, Sioux City, and Council Bluffs, stopping two days only at each place, when examinations will be had and applications received for certificates, and diplomas verified. These meetings are held for the convenience of physicians in different parts of the State. All midwives in the State are required to conform to the same rule as physicians, and secure a certificate to practice.

American Medical Association, Formed in 1846.

Next annual meeting will be held June 7, 8, 9, and 10, 1887, in Chicago, Ills.

President—E. H. Gregory, M. D., St. Louis, Mo.

Permanent Secretary—W. B. Atkinson, M. D., Philadelphia, Pa.

Assistant Secretary—J. Nevins Hyde, M. D., Chicago, Ill.

Treasurer—Richard J. Dunglison, M. D., Philadelphia, Pa.

Librarian—C. H. A. Kleinschmidt, M. D., Washington, D. C.

Chairman of Committee of Arrangements—Charles Gilman Smith, M. D., Chicago, Ill.

All membership dues should be sent direct to the Treasurer, Richard J. Dunglison, M. D., lock box 1274, Philadelphia, Pa.

A Voudooed Pillow.

A writer in the *New Orleans Picayune* tells how he met a colored woman who attributed her husband's illness to his sleeping on a "voudooed pillow." She felt the pillow and discovered the "voudoo," which felt hard. The pillow was carried to the river, cut open, and the feathers cast into the water over the left shoulder. If they assumed the shapes of animals as they floated away, the sick man would get well. In a subsequent interview, this sable lady informed the writer that the feathers floated off as dogs, cats, etc., and her husband was well.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE WEEK ENDED AUGUST 7, 1886.

Hutton, W. H. H., surgeon. To proceed to Key West, Florida, for temporary duty, August 7, 1886.

Bevan, A. D., assistant surgeon. Ordered to examination for promotion, August, 1886.

Williams, L. L., assistant surgeon. When relieved at Buffalo, New York, to proceed to Mobile, Alabama, for temporary duty, August 2, 1886.

The Outlook for the Congress.

Prof. W. F. Peck, of the Iowa State Medical University, who is now making an extended tour of Europe, writes as follows from Amsterdam to the *Jour. Am. Med. Ass.:*

"I visited Prof. Esmarch the other day in Kiel. He will come to the International Medical Congress. From what I can learn, the profession of Europe will send a large delegation. Prof. Billroth told me that he expected to attend, and Carl Braun will accompany him."

Items.

—Dr. Oliver Wendell Holmes is leaving England by the "Catalonia," which sails from Liverpool on August 24.

—Dr. Maas, the accomplished Professor of Surgery in the University of Berlin, died suddenly at Würzburg recently, at the early age of forty-three.

—The *Sanitary News* laments, on hygienic grounds, the organization in Chicago of a Company known as the "United States Hash Preserving Company."

—It had been proposed to build a large hygienic institute in Vienna, but unfortunately the means are not forthcoming at present, so the project is necessarily in abeyance.

—It is intended to establish a professorship of the Chemistry of Food in the University of Berlin. The holder of the chair is to have the rank of Extraordinary Professor.

—Professor Graskey, of Würzburg, has been called to Munich as successor to the late lamented Professor von Gudden, whose tragic end will be still fresh in the recollections of all.

—The Liebig Monument Fund amounts to 25,000 dollars, and the monument will be erected in Ziessel, a small Hessian University town, where Liebig first won fame as a lecturer on chemistry.

—A sanitary convention, under the auspices of the Michigan State Board of Health, will be held at Coldwater, on Thursday and Friday, September 9th and 10th, 1886, the time (September 23d and 24th) originally fixed for the meeting having been changed.

—It is reported that a Cleveland, Ohio, druggist, in filling an order for sugar of milk. substituted arsenic, which was administered to three children by the mother, who also took some. The mother is said to have died, and the lives of the children are despaired of.

—A person styling himself Dr. Vivian, of New York, who has for some time been victimizing the profession and the public in various parts of England, was recently arrested on a warrant for a hotel fraud. Bail was refused, and the prisoner remains in custody, "wanted" for various offenses.

—As on the 30th of August next Mr. Chevreul will attain his one hundredth year, a movement is on foot to commemorate this anniversary by a medal which shall transmit to posterity the features of the illustrious *savant*. A medal is to be presented, and a copy of it will also be sent to each subscriber.

—Eugene S. Yates, M. D., of Lawrence, Mass., died on Wednesday, July 28th. He was graduated from Bellevue Hospital Medical College in 1872, and from 1879 to 1883 he was the City Physician of Lawrence. At one time he was a member of the local board of health. His death is said to have been due to paralysis.

OBITUARY NOTICE.

Frank H. Hamilton, M. D.

Dr. Frank H. Hamilton, of New York, who was associated with Dr. D. Hayes Agnew, of Philadelphia, in the treatment of President Garfield, died August 11. The immediate cause of his death was the failure of his system to receive nutriment, but for more than three years he had been in a steady decline. His lungs had long been affected, and since December, 1883, repeated pulmonary hemorrhages had made such draughts upon his system that he had known for a year past that recovery was out of the question. With his attending physicians, Drs. Austin Flint, J. R. Leaming, and L. E. Damainville, he frequently discussed his own case, and made notes upon the progress of his malady.

He was a native of Wilmington, Vt., and would have been seventy-three years old in September next. In 1833 he graduated from the medical department of the University of Pennsylvania, and after practicing at Auburn, N. Y., and Buffalo, settled in New York city in 1862. For two years he served as medical inspector of the army during the war, and during that time laid the foundations of his fame as a surgeon, which was not excelled by that of any contemporary practitioner. His inventions of surgical appliances and contributions to the science have been more numerous than those of any other surgeon of his time. Among them may be mentioned the bone-drill, the compound Nelaton's probe, bullet forceps, a movable apparatus for fractures of the thigh, the modified Liston's artery forceps, serrated giant bone cutter, hare-lip scissors, an improvement on Owen's tonsillotome, and a method of manipulating the bodies of drowning persons. One of his most valuable contributions was his system of keys and guides to the articulations. He vastly improved the gutta percha splints, and in surgical operations of the first magnitude he made numerous daring and successful innovations. He wrote a treatise on military surgery and a general surgical treatise, beside publishing scores of articles in professional journals. He was for many years Professor of Surgery in the Bellevue Hospital, and at the time of his death visiting surgeon to Bellevue Hospital, consulting surgeon to St. Elizabeth Hospital, to the Hospital for the Ruptured and Crippled, and to various city dispensaries.

QUERIES AND REPLIES.

Fistula in Ano.

I would like to ask your readers whether they would consider it wise surgery to endeavor to heal a discharging fistulous tract about the anus, the result of an abscess, in one who has some kidney trouble, and who as a result of a reckless life is much "broken up." X. Y. Z.

Canadian Physicians.

Can you tell me how many physicians of all kinds there are in Canada? A. B. C.

We refer this query to some of our Canada readers.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

105-15556

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

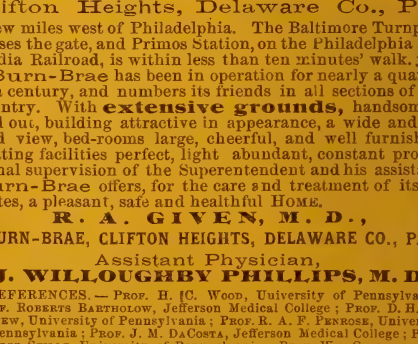
An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease-producing matter.

INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,
36 Platt St., New York.

BURN-BRAE.



This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful Home.

AT WHAT PART OF THE INTESTINAL CANAL DO ITS CONTENTS BECOME FECULENT?*

BY E. G. WATERS, M. D.,

Of Baltimore.

A question that arose incidentally at the last meeting of this Society, viz.: at what part of the intestinal canal its contents become excrementitious or fecal, seemed to me to possess so much interest as to deserve more than a passing consideration. On this account, I have given the subject some examination, and now submit the result to the Society.

Dr. Simon, in his Animal Chemistry, edition of 1846, page 574, defines the feces to be "that portion of the food which is not taken up by the absorbents which are everywhere distributed between the stomach and the large intestines, but again discharged from the system." He classifies the insolubles under the heads of vegetable fibres, flesh of old animals, sinews, ligaments, fat, bile modified, biliphæin, cholesterin, mucus, salts, ammonia, magnesian phosphates, etc. We shall find hereafter this list of substances increased or modified in some respects.

Carpenter, in his Elements, edition of 1851, page 263, at the close of paragraph 460, says: "During the passage of the alimentary matter along the small intestines, as we shall see hereafter, a large proportion of the fluid is removed by the absorbent power of the villi; and the residue is brought therefore to a more solid consistence. This residue consists in part of those portions of the aliment which are not capable of being dissolved, or finely divided, so as to be received by the absorbents; and in part of the matter poured into the alimentary canal by the various glands that discharge their contents into it for the purpose of being carried out of the body. The feces which are thus formed are propelled through the large intestine by the continued peristaltic action of its walls, until they arrive at the rectum." Berzelius, as quoted by one of the authors whom I shall cite, puts the waste from the system at twice the amount of the residue from the food in the entire fecal discharge. Again on page 421, paragraph 749, of same work, Carpenter says: "But there is a strong reason to believe that the function of the Peyerian glandulæ which beset the walls of the lower part of the intestinal canal is purely excretory, and that they are destined to eliminate putrescent matters from the blood, and to convey them, by the readiest channel, completely out of the body. That the putrescent elements of the feces are not immediately derived from the food taken in so much as from the secreting action of the intestinal glandulæ, appears from this consideration; that fecal matter is still discharged, even in considerable quantities, long after the intestinal tube has been completely emptied of its alimentary contents." He fortifies this statement by the history of many diseases when food has not been taken for many days, by "colliquative diarrhœas," by spontaneous discharges and those invited by the action of medicine, and by the active efforts of the intestinal glandulæ to get rid

* Read before the Clinical Society of Maryland.

of the decomposing elements of the body which precede death from starvation. And this view he again emphasizes, almost in the same words in his "Principles," edition of 1868, page 132. And again, on page 425 of his Elements, paragraph 758, the same writer, speaking further of the intestinal glandulæ, continues: "Whose function is not only to remove the putrescent matter ordinarily formed by the disintegration of the tissues, or by the decomposition of unassimilated food, but also to draw off the still more offensive products of changes that take place in disease."

"Before the excrementitious matter," says Dunglison, *Human Physiology*, 1850, vol. i., page 616, "reaches the lower portion of the small intestine, it has not the fecal odor, but acquires it after it has remained there for a short time. The brownish-yellow hue becomes deeper; but its consistence, smell and color vary considerably according to the character of the alimentary matter * * * The fecal matter, as we find it, consists of the excrementitious part of the food, as well as of the juices of the upper part of the canal that have been subjected to the digestive process. * * The peculiar fecal impregnation is probably dependent upon a secretion from appropriate follicles—those of Peyer, for example, and we can thus understand * * * why fecal evacuations may exist when the individual has not eaten for some time, or taken but little nourishment."

Müller, *Elements of Physiology*, 1843, page 402, says: "The mixture of chyme, mucus, bile, and pancreatic juice, becomes, in its passage through the lower part of the small intestine, more consistent and of darker color. The fluid parts are absorbed by the lacteals. All the solid matters, as mucus, skins of fruits, woody fibres, hairy matter, and resin, on reaching the lower extremity of the intestine, constitute the excrement, from which, however, the fluid ingredients continue to be absorbed during its passage through the large intestine."

Kirke and Paget, in their *Manual of Physiology*, 1853, page 203, say: "Its result (absorption) is that the mixture of chyme and various secretions is generally made more consistent and darker, and at the lower end of the small intestine contains little more than the insoluble and indigestible matters, such as starch, woody fibre, hairy matter, epithelium cells, and mucous corpuscles, epidermis of both vegetable and animal tissue, crystals of ammonia, magnesian phosphates, and other salts, the coloring and fatty matters of the bile, and other excrementitious substances."

Dr. John William Draper, *præclarum nomen* in Medical Sciences, in his Human Physiology, 1856, page 83, writes as follows: "As the digested mass passes onward * * * it becomes of a more solid consistency as the absorbents gradually remove its liquid portions. * * * From Peyer's glands a secretion has exuded which perhaps gives to the mass the characteristic odor it is now assuming, if indeed these organs are not connected with absorption. The excrementitious remains are colored yellow by the coloring matter of the bile, and are partly derived from the undigested residue of the food and partly from the decay of the system itself."

Dalton, in his Human Physiology, 1861, pages 142–3, says: "Digestion of food goes on continuously through the small intestines, producing three different substances: 1. Albuminose, from action of gastric juice on albuminoid matter. 2. Emulsion, from pancreatic juice on fat. 3. Sugar, from starch acted on by mixed intestinal fluids. These products of digestion are removed from the tract by the absorbents. Below the ileo-cæcal valve the contents change in their odor, color, and consistency. This portion of the intestinal contents, or the feces, are not composed, for the most part, of the undigested remains of food, but of animal substances excreted by the mucous membrane of the large intestine." This writer calls attention to the fact that Dr. Marcet found the most important constituent in the large intestine to be excretine. It will be observed that Dr. Dalton ignores entirely the residuum of the food, together with the glandular and follicular excretions that exist in such abundance in the ileum and escape from it through the ileo-cæcal valve, as contributing largely to the contents of the large intestine.

Carpenter, in his Principles, edition 1868, page 131, says: "Although it cannot be stated with certainty what is the precise portion of the glandular apparatus connected with the intestinal canal which is concerned in the elimination of that peculiarly putrescent matter which gives to feces their characteristic odor, yet it may be stated, almost with certainty, that this matter is not derived from the decomposition of the undigested residue of the food." And at page 132 of the same book, he quotes Liebig's experiments to the effect that albuminous matters heated with solid hydrate of potash, the heat being continued until most of the nitrogen is driven off as ammonia, and hydrogen begins to be given off, the residue being supersaturated with dilute sulphuric acid and then distilled, yield a liquid containing acetic and

butyric acids, and possessing in an intense degree the characteristic odor of feces. "As the action of caustic potash at high temperature is simply a limited or incomplete oxidation or combustion, this curious result confirms the view that had previously been put forth by Prof. Liebig, that the proper fecal matter is the product of the imperfect oxidation which a portion of the histogenetic constituents of the food undergo, the course of their retrograde metamorphosis being comparable to the soot or lamp-black of a furnace or lamp." It is further remarked that this odor disappears on exposure to the air and complete oxidation.

Dr. Reese, in his Analysis of Physiology, 1852, pages 205–6, states that, "The functions of the glands of Brunner and Peyer is not perfectly known, but there is a strong reason for belief that it is purely one of excretion. * * * No doubt much of the fecal matter is derived from these glands, for we see it discharged from the bowels when no food has been taken." Flint's Physiology of Man, 1868, regards stercorine and excretine as giving to the feces their distinguishing characteristics. The first was recognized by Baudet in 1833, in the serum of the blood, and by him called seratine. Flint considers it as the changed condition of cholesterine, and claims to have discovered it in the feces in 1862.

Foster, one of the latest and most exhaustive writers on this subject, in his text-book, 1880, pages 314, 315, 316, says: "These products (fats, sugar, peptones, lactic acid, etc.), as they are formed, pass either into the lacteals or the portal blood-vessels, so that the contents of the small intestine, by the time they reach the ileo-cæcal valve, are largely, but by no means wholly deprived of their nutritious constituents. * * * We have already seen that during artificial pancreatic digestion a distinctly fecal odor, due to the presence of indol, is generated; and the fact that the presence of bacteria, or other similar organisms, is essential to the presence of this body does not preclude the possibility of it, with its derivations, being the chief cause of the natural odor of feces, for undoubtedly bacteria may exist throughout the whole length of the intestinal canal. At the same time, it is quite possible, if not probable, that specific odoriferous substances may be secreted directly from the intestinal wall, especially from that of the large intestine. Birger finds indol and skatol, the latter in large quantity, in excrement." Nevertheless, on page 314 of the same volume, Foster seems to cancel one of his most important inferences in the above quotation, for he says: "Whether digestion, properly so-called, is all but complete at the ileo-cæcal valve, or whether important changes await the chyme in the large intestine, the chief characteristic of the work done in the colon is absorption." If this be true, the secretive functions of the mucous surface of that intestine must be suspended for the most part during the passage of the contents of the canal through it.

In the *American Journal of the Medical Sciences* for July, 1860, page 217 *et. seq.*, will be found an analysis of a most interesting case of intestinal fistula reported by Prof. Busch, of Bonn. It was that of a woman, aged 31, who had been gored by a bull. An opening subsequently took place in the "upper third of the small intestine (Foster says in the duodenum, but this is not stated in the analysis, but, on the contrary, contraindicated), which remained permanent. The opening was about one and one-fifth inches in length, and through it escaped, and were received for examination, matters that had come through the pylorus, and into it were introduced many forms of aliment designed to be subjected to the action of the intestinal juices in the lower part of the canal. Among the many points of interest in this case, I note three which are especially pertinent to the subject of this paper.

1. On numerous occasions articles of food that were distinctly recognizable made their appearance at the upper orifice in fifteen minutes after being swallowed.

2. A reversed peristaltic action at times brought back to the opening various aliments after the expiration of several hours from the time they had been introduced into the lower part of the bowel; and,

3. There is no mention whatever of a fecal odor to the dejections.

A highly offensive and putrid odor is noted as pertaining to the dejections in several cases, but in no instance that I recall was the fecal odor distinguished in them. It should be remembered that in no case did food, after being swallowed, pass beyond this opening.

Now, the sum of this whole matter is this, that here, as in so many departments of physical study, our ignorance is humiliating after the immense time and labor given to the subject by able and conscientious men, who were and are not mere makers of books. Nevertheless, the weight of evidence is largely in favor of the supposition that the contents of the small intestine before they are pushed beyond the ileo-cæcal valve are

probably, as a rule, wanting in no feculent feature, unless it be that of mere solidity. If the contents of the small intestine are not excrementitious, how is it that in stercoraceous vomiting such matters are brought up, if, as some experimentists tell us, the ileo-cæcal valve is impervious to the return even of liquids from beyond it? And if the chief office of the colon is absorption, according to Foster, how does so considerable an accumulation of feculent matter take place in it, when we remember that Berzelius estimates the residue from food at less than 33 per cent. of the entire mass? To these and other similar questions it seems to me there can be but one answer.

THE TERMINATION OF 2,221 CASES OF INSANITY OF SUPPOSED SOMATIC ORIGIN.

BY T. M. T. McKENNAN, M. D.,

Of Dixmont, Pa.

Assistant Physician Western Pennsylvania Hospital for the Insane.

Statistics are not altogether reliable, and especially is this the case with regard to statistics concerning insanity. Relying as we frequently must on the statements of friends of patients, whose information is often meagre and whose statements are only partly true, desiring as they do to cover up individual and family weaknesses and faults, we are often at sea with regard to causation. The bearing of causation on treatment and prognosis is great.

The following statistics are gathered from carefully taken records, and are probably as nearly correct as could be attained.

These include all the cases of somatic origin admitted and treated in that hospital for thirty years whose causation comes under the nine different heads. Alienists differ with regard to the relative importance of physical disease in the causation of insanity, but all agree that it is a factor.

The list of causes is as follows: epilepsy, syphilis, acute febrile conditions (insanity termed post febrile), intemperance, excesses, puerperal state, menopause, sunstroke, and general ill health.

Epilepsy.

Puerperal	48%	24%	17%	11%
Menopause	20%	37%	21%	22%

Epilepsy.—The termination is thus shown to be very unfavorable. Only 6 per cent. recovered; 42 per cent. died; 66 per cent. of the cases had been affected for three years or over. Only upon the development of violent epileptic mania are these cases sent to asylums. Mild and recent cases are seldom confined in asylums. When the epileptic habit has become thoroughly established, therapeutic measures are seldom curative, but merely palliative.

Syphilis.—These cases include all forms of insanity due to syphilis. *Mania and melancholia* due to thickening of the membranes or to nutritive changes in the cortical blood vessels, thus affecting the cortical cells. *Dementia* due to gummatous growths or sclerosis of cerebral substance.

Post-Febrile.—Insanity following an acute febrile condition, as small-pox, erysipelas, measles, and typhoid fever. Termination: 31 per cent. recovered; 35 per cent. improved; 18 per cent. not improved, and 16 per cent. died. 58 per cent. were classified as mania, 34 per cent. melancholia, and 8 per cent. dementia.

General Ill Health.—Under this head are included cases of general debility, anæmia, pulmonary affections, functional and organic kidney and liver affections, and all forms of general or local disease not otherwise classified. This method of classification is not strictly scientific, but is probably as nearly correct as could be attained. 35 per cent. reported recovered; 30 per cent. improved; 16 per cent. not improved, and 19 per cent. died. 60 per cent. are classified as mania, 36 per cent. melancholia, and 4 per cent. dementia.

Intemperance.—This is a prolific source of insanity. Two sources of error are liable to arise:

1. Friends attributing the insanity to a moral cause, and concealing the fact of intemperance.

2. The intemperance may have arisen since the attack of insanity, thus aggravating and causing the insanity to be more obvious.

General paretics are almost invariably given to intemperance during the first stage of their disease, when insanity is hardly recognizable. Termination: 42 per cent. recovered; 17 per cent. died.

Excesses.—We include under this head sexual excesses and masturbation; also, cases of excesses in opium and chloral combined with alcoholics. The same sources of error are liable to arise as in intemperance as a cause of insanity.

Nearly all the cases of general paresis are classed under this head, from the fact that during the first stage of their disease general paretics are given not only to intemperance, but to excesses of all kinds. 41 per cent. had a duration before admission of three years or over; 26 per cent. recovered; 28 per cent. improved; 25 per cent. not improved, and 21 per cent. died.

Sunstroke.—The termination is better than, from the nature of the cause, we would be led to expect. Forty-one per cent. recovered; seventeen per cent. improved; sixteen per cent. not improved, and twenty-two per cent. died. The cases, however, are not numerous, only thirty-four being recorded.

Puerperal.—We include under this head all cases of insanity occurring during the puerperal period, whether occurring shortly after conception or during lactation. Cases seldom occur earlier than the fourth month of pregnancy. While the maniacal condition preponderates as the form of insanity assumed, sixty-nine per cent. being thus classified, still the melancholic condition occurs in thirty per cent., and dementia in one per cent. of the cases. The termination agrees with the experience of many alienists, viz., more favorable than any other form of insanity. Forty-eight per cent. recovered, twenty-four per cent. improved, seventeen per cent. not improved, and eleven per cent. died. Mortality less than in any other form.

Menopause.—The occurrence of insanity at this period, when physiological changes are taking place in the organism, renders the termination unfavorable. Twenty per cent. recovered, thirty-six per cent. improved, twenty-one per cent. not improved, and twenty-two per cent. died. The mortality is large, and the prognosis far more unfavorable than insanity occurring during the puerperal state.

The "whole duration" in the tables of puerperal insanity and insanity occurring at the menopause means the duration before admission plus the time the cases were under observation. Fifty-five per cent. of the cases due to the menopause were classified as mania, thirty-four per cent. as melancholia, and one per cent. as dementia.

The average mortality from all the causes is twenty-two per cent.; a large mortality, yet not larger than one would expect to find from the nature of the causes, as many cases are found to have undergone such extensive structural changes that physical recovery is impossible, and the whole tendency is towards death.

THE PERINEUM AS A SUPPORTING STRUCTURE.*

BY C. D. PALMER, M. D.,

Of Cincinnati.

Professor of Gynecology, Medical College of Ohio.

The author, after ascribing to Ambrose Paré due credit for having first devised and executed an operation for the cure of laceration of the perineum, reviewed the list of names that had been prominent in advancing the operation toward perfection, and entered into the discussion of the question, To what extent is the perineum a supporting organ?

This he considered one of the mooted questions of the gynecology of to-day. Within recent years there has been a growing tendency to discard, at least in a measure, the direct supporting power of which we have been supposing this body possessed. The author recalled to mind three cases of complete laceration of the perineum which had lasted 36, 20, and 10 years. In no case was there any uterine or vaginal displacement. The question might be very pertinently asked: Why, if the perineum is such a needful support to the vagina and superincumbent viscera, do the vaginal and uterine displacements invariably follow after years of practically total destruction of its integrity? Why do we so frequently have great and serious displacements of these organs, when the perineum proper has suffered little or no injury? 1. The perineum does not possess that supporting force claimed by some for it. 2. Other factors than its injury lead to displacements. Emmet, Schatz, and Duncan, are prominent among those who have expressed views against the supporting power of the perineum. The uterus obtains no direct support at all from the perineum. This organ is suspended in the centre of the pelvis through the pelvic floor. The perineum lies largely below the pelvic floor. It is injury of some kind, over-distension, undue stretching, laceration in some part of the levatores ani or pelvic fascia, separation of these muscles in their central connection, injury of some sort to the structure where the anterior rectal joins the posterior vaginal wall, all largely confined to parturition, that we are to look to for the real and immediate cause of most cases of uterine displacements.

It will be safe, I think, to formulate the following propositions:

1. As the perineum is made up of muscular and other tissues, entering into the lower structure of the floor of the pelvis, it follows that lacerations of it do impair, both directly and indirectly, the forces which sustain the vagina, and through this organ, the bladder and rectum.

2. Perineal lacerations, even complete ones, may occur and not be followed by displacements. Complete splitting of the sphincter ani, leading or not to rectal incontinence, greatly diminishes the chances for vaginal displacement, in that it lessens ordinary intra-abdominal pressure at rectal evacuation. The absence of any change in the vaginal walls implies that the laceration, however extensive, has involved to a great extent only the base of the pyramidal body.

3. Perineal lacerations do not produce uterine dislocations directly. Through vaginal subinvolution, the formation of a rectocele, a cystocele, then traction upon the pelvic floor, they may do so indirectly.

4. Uterine displacements to a great degree, and vaginal displacements to considerable though less degree, are due to a weakening of the pelvic floor or diaphragm (from which the first-named organ is suspended), by injuries sustained chiefly during parturition, but aggravated by causes operative afterwards.

Good results in perineorraphy, as in plastic and uterine surgery, depend upon the attention to many little details, before, during, or after the operation itself. But aside from all these, the two chief features of the operation consist of a thorough denudation of a surface, proper in size, shape, and location, and the correct adjustment of the sutures. Two very common errors are made—one to denude the vulvar orifice too far forward and to take off too much skin; the other not to extend the vaginal dissection sufficiently upward.

Thorough and complete coaptation of the undenuded borders of the two lateral denuded surfaces can be effected only by the use of vaginal sutures. These may be so placed as to not only bring these borders together, edge to edge, but take up and bring into apposition the ruptured, separated muscular fibres and deep pelvic fascia of the perineum and pelvic floor; to reconstruct a

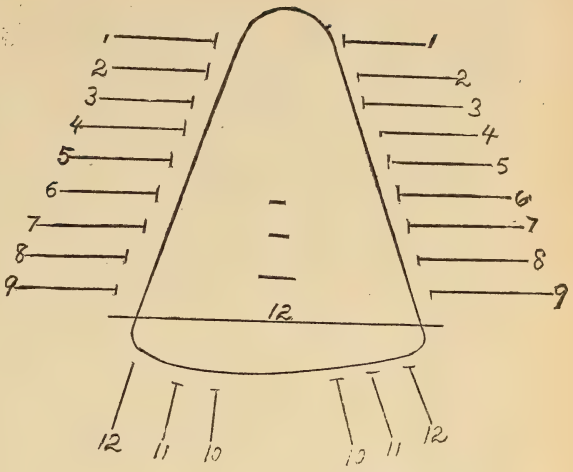
SHORTER TRIANGULAR DENUDATION.



LONGER TRIANGULAR DENUDATION.

new pyramidal body, in substance to fill the normal interspace between the rectum and vagina—a body not only wedge-like in shape, but wedge-like in action, the true function of this structure.

Suture No. 9 enters the integument and makes its exit on undenuded mucous membrane in the vagina about one-fourth inch below No. 6. When the triangle is folded together, all this suture, shown running across the base of the triangle, is drawn out by tightening the outward ends.

The external sutures are removed in from seven to ten days; the vaginal in from ten to fourteen days.

The advantages of this method of placing the sutures (the greater number by far being intra-vaginal, not external) are: less after-swelling and pain, greater ease in self-urination, and little or no pocketing of the posterior vaginal wall within the vulva. In my experience, a thicker, stronger perineal structure is built and a better vaginal support is given than by any other operation.

The operation, as described by the author, would, he felt sure, prevent sagging of the posterior vaginal wall and pelvic floor, by reuniting its muscular and fascial connections, thus largely, if not entirely, restoring the functions of these most important structures.

HÆMATURIA MIASMATICA.

BY J. EDWARD STUBBERT, M. D.,
Of Bloomfield, N. J.

In a recent number of your journal an article appears entitled "Malarial Hæmaturia." The writer claims, or intimates, that his plan of treatment is par excellence the mode to be adopted. From a rather extended experience with the disease in question, in the State of Florida, I am prepared to say that *all cases are amenable to treatment by quinine, if such treatment be entered upon within thirty-six hours of the onset.*

As this peculiar disease is not widely known, I will state briefly that it occurs only in those persons who have been for a long time subjected to slow malarial infection without the proper administration of quinine. So nearly does the general appearance of the patient resemble that of one with yellow fever, that some *superficial* observers have named the disease "highland yellow fever."

The distressing symptoms are hæmaturia, intense nausea and black vomit, extreme thirst, frequently repeated chills of a congestive character, and, at times, sinking turns amounting almost to syncope. The other symptoms are those common to all other cases of remittent fever. In fact, I believe the disease in question is simply an aggravated form of remittent fever.

Owing to the severe gastric disturbances, it is impossible to exhibit quinine in sufficiently large doses per orem, hence it is my custom to administer hypodermically ten (10) grains of the bisulphate of quinine (three times a day at least). The object being thoroughly to cinchonize the patient, the frequency of the dose will depend upon how readily that end is attained.

My friend, Dr. Geo. Troup Maxwell, of Florida, is in the habit of combining with each injection of quiniæ bisulph., gr. $\frac{1}{8}$ of morphiæ sulph.

Saline diuretics seem to me to act well by relieving the kidneys by flushing. As soon as the patient becomes thoroughly cincho-

nized the temperature begins to fall, the urine becomes clear, all other symptoms ameliorate, and the patient goes steadily and rapidly onward to the stage of convalescence. I have never lost a case treated in this manner within thirty-six hours of its incipiency. Dr. Maxwell has met with equally good results, and in a larger number of cases.

The position taken by some that "pure blood" is passed from the kidneys seems to me untenable. It is impossible for a reasonable physician to believe that quantities of blood so great as some claim could be lost daily and the patient still live. Is it not more reasonable to suppose that the evacuations are urine, colored by the coloring matter of the red corpuscles which have been disintegrated by the high temperature, and by loss of plasticity in the blood allowed to exosmose into the urine?

OPERATING DURING THE SAME ANÆSTHETIZATION FOR LACERATIONS OF THE CERVIX UTERI AND RUPTURED PERINEUM.

BY THOS. A. ASHBY, M. D.,

Professer of Gynecology in the Baltimore Polyclinic and Post-Graduate Medical College, etc.

The two most important lesions of childbirth—laceration of the cervix uteri and rupture of the perineum—are frequently associated in the same individual. We may readily account for this coincidence by the fact that the causative influences which tend to produce the one are also, in the majority of cases, at work to produce the other. Statisticians have vigorously compiled tables to show the great frequency of cervical lacerations, but no facts are available to show the relative frequency of perineal ruptures. The difficulties in the way of the collection of reliable data bearing upon this point are quite apparent. Unless we except ruptures through the sphincter ani, the lesions of the perineal body are about as difficult to classify in tables as are the spots on the moon. From a slight abrasion of the fourchette to the complete destruction of the perineal floor back to the anal sphincter, an endless variety of lesions may be observed, which have more or less significance according to their influence upon the subsequent health of the patient. Lacerations of the cervix uteri are more pronounced, and are more apparent to the experienced observer. The slightest lesions of the cervix more readily unite by primary union than the slight perineal tears, from the fact that the wounded surfaces are less exposed to the secretions and accidents which tend to defeat union by first intention. It is from the difficulties in the way of classification that figures are wanting to show the frequency of the perineal lesion, and the relative frequency with which these lesions occur at the same time in the same individual.

Without then calling to our aid statistics to show the common occurrence of the two lesions in the same individual, we assume this fact as a part of our experience, and pass to the consideration of the treatment of the two lesions at the one anæsthetization. In our early professional experience, the two operations, when required in the same individual, were performed at different periods, the interval extending as long as six weeks or as many months. This method of practice was based upon the precedent of high authority, and upon circumstances which were believed to exercise a more favorable influence upon the two operations as thus performed. Following the example of Sims, Emmet, and other recognized leaders, the silver wire suture was exclusively employed in our earlier experience, and it is in great measure to this practice that we must refer our allegiance to the separation of the procedures by long intervals of time. The cervix operation was first performed, the patient being anæsthetized, and eight to ten days were allowed for union before the wire sutures were removed. During all this time the patient was kept in the recumbent posture. After the removal of the sutures, a number of weeks were permitted to intervene before the perineal operation was approached. In the meantime hot water douches, tonics, etc., were advised in order that the patient might be placed in the very best condition for the second procedure. A second anæsthesia and the details of a second operation were now gone through with for the closure of the perineum, and eight or nine days of subsequent nursing and not infrequently as many weeks of subsequent convalescence were the outcome of the second procedure.

The details and disadvantages of this method of operating are as real as they are apparent. The effects of two separate methods of procedure upon the patient were far from salutary, whilst to the operator the anxiety and labor were more than twofold. After an experience, with the methods of separate procedures, we were not regretful when an opportunity came to abandon them.

This opportunity presented itself when the catgut suture became one of the popular additions to our armamentarium.

Having tenaciously held on to the silver suture we were loath to abandon it for its now more popular rival; but the acceptance of the new for the old worked a complete change in the method of operating, and has so modified our views in regard to the treatment of these two lesions that we now occupy an entirely different relation to them. Latterly, we have invariably practiced the method of closing both lesions whilst the patient is under the influence of the anæsthetic, with results so simple and satisfactory that we seldom see just ground for separating the interval between the two operations.

The method of proeedure is this: The patient is first prepared for operation by as many days or weeks of prior treatment as her condition demands. When she is in suitable health, a day is set apart and the early morning selected, say the hour of 10 o'clock, for the operation. The patient is anæsthetized, and then placed in Sims' position. The edges of the torn cervix are properly pared and brought together with antiseptic cat-gut sutures. Beginning at the angle of the flaps, the sutures are passed in parallel rows and as near to each other as they can be conveniently inserted. Three, four, five, or six sutures, or more, if required by the length of the flaps, are employed. The wound is now brought into close apposition and the sutures are tied, commencing with the one nearest the angle of the wound. After the flaps are in this way drawn together and adjusted, a single wire suture is passed through each flap at the cervical opening. This is twisted to the required degree, and the ends so cut off that the end-points cannot irritate or wound the vaginal tissues. This is best accomplished by converting the wire into a spiral and turning the end-points into the hollow of the spiral. The wire sutures are used as fixation sutures and on the theory that the strain upon the suture is greatest at the end of the cervical stump. It has never been found necessary to use more than the single wire suture, though in a case of an unusually long flap or very thick cervix either silk or wire would be employed if necessary. The catgut suture has acted very satisfactorily in our experience. By the end of the eighth or tenth day it will most probably have disappeared by absorption, but in this there is an evident advantage. Primary union must result in from 48 to 72 hours, if it takes place at all, and the cat-gut suture, if of any value at all, will continue to hold the flaps in apposition until this time. We have found the cat-gut suture in position as late as the fourteenth day after the operation.

Having closed the cervix after the manner described, the patient is changed from Sims' to the recumbent posture, the perineal border is abraded of its mucous surface, and the tissues are brought together after the method of the perineal operation as advised by Dr. Emmet, or such modifications of it as may be indicated in the case. The perineum thus closed, the patient is lifted into her bed and treated as after an ordinary operation for the closure of the perineal body. At the expiration of eight days the perineal sutures are all removed. The wound is bathed in antiseptic washes, and the vagina is likewise syringed out with antiseptic injections. The patient is enjoined to remain quiet for the next five or six days, and usually by this time the perineal wound is so far well that the finger or speculum can be used to examine the cervix. Usually the sutures from the cervix are removed on the fourteenth or sixteenth day after the operation. Convalescence is rapid after this. During the operation, every attention is given to cleanliness, and antiseptics—chiefly the bichloride of mercury 1 to 4,000—are carefully employed. Hemorrhage has never proved to be a troublesome complication of the two procedures. The time required for both operations is from one hour to one hour and a half. This can be expedited by having an abundance of needles, sponges, and other instruments required for expeditious work. If the operator stops in the middle of an operation to talk, or to thread needles, or to sponge, he should not charge this delay to the operation. He should have assistants and nurses to hand him instruments and to render necessary attentions, thus avoiding a very tedious and tiresome procedure. The results of these operations by the method here related have been just as satisfactory as by the old method in point of relief afforded the patients, whilst from the standpoint of comfort to patient and operator the gain has been immense.

By the conjoint method we gain, *first*, the closure of two lesions whilst the patient is under the anæsthetic. This is in itself a most important advantage to both patient and operator. We gain, *secondly*, a period of confinement to bed of about two weeks, and a single convalescence, as compared with the weeks given to the operation at separate intervals and the anxiety and dread —born of experience—which were insepara-

ble from this method. In the *third* place, we save time and suffering by condensing two grave procedures into a single procedure which does not increase the danger in proportion to its apparent gravity, *Fourth*, the results of union are just as satisfactory by the new as by the old method.

Medical Societies.

PHILADELPHIA CLINICAL SOCIETY.

Stated meeting, April 23, 1886. The president, Dr. John B. Roberts, in the chair.

Dr. Edward R. Stone reported a case of

Extravasation of Urine Followed by Repeated Aspiration of the Bladder.

More than three years ago I was called to J. W., æt. 67, who was suffering from retention of urine. He gave the following history: He had always been very healthy, until he began to suffer from difficulty in passing water. This had lasted for some time, and was attributed, by him, to working in wet places, his duties as engineer at the water works often requiring him to stand in water, and expose himself to taking cold. He had never before had total retention, but the urine often came drop by drop, and was voided with great difficulty. By the rectum the prostate was found to be very decidedly enlarged. After patient efforts with various catheters, the bladder was reached by the manœuvre of passing a flexible instrument with the stylet to the seat of obstruction, then, by slightly withdrawing the stylet, the point of the catheter was made to mount over the enlarged third lobe. The patient was instructed in the use of the catheter, and copaiba was found of benefit in relieving catarrh of the bladder, which was aggravating his complaint. From time to time it was necessary to give him assistance when he failed to catheterize himself. Efforts to reach the bladder were always successful until the night of September 17, 1885, when he was found suffering again from retention. He had already tried the catheter, but unsuccessfully, and had injured the urethra by using an instrument which was partially broken, and allowed the wire to protrude. Careful and repeated attempts were made during the night to reach the bladder. These failing, Dr. W. W. Keen was called in consultation. It was then decided to aspirate the bladder. This was done with a medium-sized instrument, and about one pint of urine withdrawn. By night the re-accumulation was distressing the patient again, and the aspiration was repeated at 7:00 p. m., and again at 8:00 a. m., next day. Urine withdrawn amounted to rather more than one pint for the two operations; was clear, but rather dark in color. The first puncture was in the middle line, and a short distance above the pubes, and the second and third were close to the first. A circle with a radius of one-fourth inch would have included them all. September 18 (day after first aspiration), at 4:00 p. m., I was informed that the patient felt better, as some urine was passing. Examination showed that no urine was escaping from the urethra, but it was welling up drop by drop from two of the three punctures, having displaced the adhesive plaster covering them. The bladder could be felt to extend almost to the umbilicus. The aspirator was used again, and although the puncture was made in the same neighborhood as before, and the trocar appeared to enter the organ, no fluid could be withdrawn, except a small amount of bloody serum. Dr. Keen was called again, and the patient was given ether preparatory to the operation of cystotomy. Under the influence of the anæsthetic, however, Dr. Keen succeeded in passing a silver catheter with prostatic curve, and more than one pint of urine escaped. The bladder was thoroughly washed with water, and the catheter secured in place. Above the pubes a free incision was made through the skin and subcutaneous fat.

The patient did well until the third day, when symptoms of sloughing of the deep cellular tissue became prominent. An offensive discharge began from the wound, and the deep tissues could be seen to be dead and sloughing. At the same time there was moderate fever. The catheter was left *in situ* for four days, and the bladder was frequently washed (three times daily) with a warm solution of borax. After the removal of the catheter there was no further trouble in introducing it, which was done four times in the twenty-four hours, and the bladder washed as before. The sloughing of the deep connective tissue became quite extensive, extending beneath the muscles on both sides almost to the iliac crest, and for a considerable distance above the incision. The sloughing tissue was drawn out and removed as fast as it became loosened, and carbolic acid solution was injected through a soft catheter passed in various directions under the undermined structures. Patient's strength failed rapidly under fever and diarrhœa due to septicæmia, but he rallied as the abscess

became clear of sloughing tissue and began to heal, but he sank, and died of exhaustion October 11, twenty-four days after the extravasation of urine occurred. The wound had almost healed, and although he had not been able to void his urine, the bladder remained free from catarrhal complication. No post-mortem.

Without doubt the patient's death was at least indirectly due to the escape of urine through the punctures in the bladder, infiltrating and causing to slough the deep connective tissue. Is it good practice to trust to repeated aspirations? Our case demonstrated, I think, that even the small puncture of the needle may be stretched open, as the bladder again distends, to a sufficient extent to permit urine to escape into the surrounding tissues.

Again, it should not be decided that a catheter cannot be passed until the attempt has been made under an anæsthetic. In this case the instrument was passed after the patient was under the full influence of ether, when it could not be made to enter the bladder without the anæsthetic. Much organic obstruction, plus even a slight amount of reflex spasm, may baffle the surgeon, when with the latter condition annulled by anæsthesia, success may crown his efforts. In this connection, however, it must be borne in mind that the urethra had had complete rest from all manipulation for more than thirty-six hours before Dr. Keen succeeded with the catheter.

Dr. Stone also reported a case of

Spontaneous Cure of Empyema

as follows:

G. H., boy, æt. 2 years and 9 months, has always been healthy except a convulsion at 7 months, due to indigestion. Had a slight cold for a few days, until March 1, 1885, when he was feverish and had a severe spasm in the afternoon. Fever, cough, and restlessness continued, but it was not until March 3 that a diagnosis of pleurisy could be made, his restlessness and excitement preventing an examination of the chest. On that day the respirations were rapid and evidently suppressed, and he complained constantly of pain in his belly. A friction sound could be plainly heard over the lower lobe of the right lung in the axillary line. March 9 the right chest was distended to a point about midway between the nipple and clavicle, and to a corresponding point behind, after which the effusion gradually declined with the cessation of the fever and general improvement in the child's condition.

Early in May he was taken to the country, at which time his condition was fair, although he still coughed and the lower part of his chest remained dull, with impaired respiratory movement.

I saw no more of him until November 23, 1885. He was then weak and thin; anorexia complete. Daily fever, night sweats, with painful cough when recumbent. The right chest was largely distended, intercostal spaces obliterated, flatulency except in the extreme upper part of the chest. An operation was urged, but the parents hesitated and wanted time to consider it. On November 25 I was sent for and found that a large swelling had formed just below the right nipple, measuring about 4 inches in its greater diameter. This fluctuated and became tense when the child cried, evidently marking the escape of pus from the pleural cavity.

Dr. Heilman saw the case with me, and although there were two points where the abscess was about to break, we agreed to withdraw the fluid in the usual way, with the aspirator, in order, if possible, to prevent the escape of pus in front. The chest was punctured in the sixth interspace, in a line with the posterior border of the axilla, and a little less than one pint of brownish, inodorous pus withdrawn. The abscess cavity in front became flaccid and empty, and pressure was made over it with a compress and adhesive plaster. The patient's general condition was much improved by the operation, and all went well until the fifth day, when the skin over the abscess gave way in two points, and the child's clothing was found drenched with the discharge. On taking off the dressings, two round openings about $\frac{1}{8}$ inch diameter were found, through which the air was whistling back and forth with every respiration. The openings were covered with valves of adhesive plaster, as I feared the draft through them would suck in some particles of threads of the oakum, which was applied to absorb the pus. No other application than this was made. The discharge of pus continued very free for several days, then gradually became less profuse and more watery, and after one month entirely ceased. It remained throughout perfectly sweet and inodorous. The patient's condition rapidly improved, and he is now entirely well, except that there is some dullness posteriorly, with rather feeble respiration in the lower lobe. This case is of interest as showing what might be called the natural history of empyema; it is remarked as demonstrating that the air is not always

charged with déadly germs which must be destroyed by antiseptic solutions. The ordinary air had free access to the pleural cavity of this boy for many days, without causing the least disturbance. What a brilliant triumph this would have been for antiseptic surgery, if I had decided to enlarge the sinus and wash out the pleural cavity with antiseptic solution, instead of adopting a purely expectant plan of treatment!

Dr. Stone then reported a case of

Recovery from Severe Diphtheria, with Numerous Complications.

W. H., æt. 4 years, healthy boy, but slender, and not very robust. His mother's family is consumptive, and she has a tendency to phthisis in left apex.

On December 7, 1885, he was noticed to be dull and feverish. On the 8th, moderate fever and languor. Throat red, with false membrane on both tonsils.

On December 10, the deposits had extended until they completely covered fauces and pharynx. Fever moderate. Pulse 120 and feeble. Is dull and apathetic.

December 12. No change in throat; serous discharge issuing from the nostrils, which were observed to be lined with diphtheritic membrane as far as could be seen. Respiration entirely through the mouth. The child's strength rapidly failed until December 15. He lies quiet in a somnolent state, and is with difficulty aroused, and refuses to attempt to swallow anything. Pulse 140 per minute and feeble. Temperature (a. m.) 102°. He remained in this desperate condition for about forty-eight hours, when he slowly revived. General condition better, but the nose and throat still thickly covered with deposit. He attempts to drink a little water. By December 20 there was decided improvement, the throat clearing and one nostril becoming pervious. Is taking milk and stimulants freely. Fever less; pulse 120 and stronger.

December 23. Fresh access of fever in the evening, and violent excitement and restlessness. He rolls his head continually, and moans as if in pain. Again refuses to swallow anything. Fever and pain continued with evening exacerbations, and on December 25 a discharge was discovered issuing from the left ear, and the mother asserted that he was quite deaf.

December 26. Both ears discharging and patient quieter; moderate evening fever. Both nostrils seem quite clear. He can, with difficulty, be persuaded to take liquids, much of which, however, returns through the nose. The throat is free from deposit, but there is evident paralysis of the palate muscles.

After the above note he gradually improved, but from January 2 to 8 there was great irregularity of the heart's action. Examination of the ears from time to time showed a succession of furuncles deep in the meatus, which entirely concealed the membrana tympani.

On February 1, he began to cough, but examination was negative in results. He has fever in the evening and night, with sweating toward morning.

February 3. Cough very troublesome at night, and painful. Patient evidently suppresses cough, and complains when handled; but auscultation only reveals a few coarse rales. Respirations 40 per minute. Pulse 110. He is losing his appetite, and sleeps badly. Fever remittent (99° to 100° a. m., 102° to 103° p. m.).

February 5. Signs of effusion in the right pleura; no friction sound detected.

February 12. Effusion reached its maximum; dullness to a point midway between nipple and clavicle, in upright position, subsiding to a much lower point when recumbent. After this the effusion rapidly disappeared, and was associated with a serous diarrhœa and free evacuation of urine, his general symptoms improving pari passu.

February 19. Effusion about disappeared, some dullness, however, remaining at the base of the lung, with feeble respiratory sounds. The ears continued to discharge in a lessened degree, and hearing improved. About the middle of March he began to be able to stand alone, but it was several days before he was able to walk. About the same time he commenced again to use simple words, the power of speech having been in abeyance ever since he became very ill. Emaciation was extreme, I have never seen a person more wasted; but flesh was resumed rapidly during convalescence. Dr. Heilman examined the ears with me, and found evidence of middle ear disease with perforation.

Condition April 17, 1886: Looks almost as well as before illness, but is somewhat thinner. Ears have ceased to discharge, and there is very little impairment of hearing. He has no cough, but his breathing is rather rapid, especially after exertion. The right chest is somewhat impaired in movement, and there is slight dullness on the right posteriorly, with feeble respiratory murmur. Respiration on left exaggerated. His appetite is not so good as during the early part of convalescence, but drinks milk freely. Is bright and playful.

The treatment in this case may be summarized as follows: Tinct. ferri. chlor. and hydrarg. chlor. corrosiv. by the mouth, quinine by suppository. The almost constant employment of a spray from a steam atomizer of a solution of carbolic acid in lime water, and the injection of the same frequently into the nostrils, followed by insufflation of sulphur. Whisky (max. dose ʒiij in 24 hours) with milk. Insufflation of boracic acid and later iodoform for the otorrhœa. Tinct. digitalis was given freely when the heart failed, and digitalis and ammonia with iodine externally were used to combat the pleurisy. Too much credit cannot be given to the mother's devoted and unremitting attention. Her efforts to save her only child never faltered, and while he lay in a semi-conscious state she patiently administered drop by drop from a medicine dropper, whisky and milk, which trickling into the throat would be unconsciously swallowed. I believe that these homœopathic doses of nourishment were sufficient to tide him over a critical period during which he would have succumbed under less assiduous nursing.

In the discussion which followed the reading of Dr. Stone's cases, Dr. Bruen spoke of a case in which an over-distended gall-bladder was aspirated with a very fine needle. Peritonitis set in, which terminated fatally. He feels as though he would like to be sure that the gall-bladder and peritoneum were adherent before using the aspirator.

He mentioned two cases of empyema in adults in which the aspirator was used, pus withdrawn, and after a few months there were evidences of thickened pleuræ. He has resorted to resection of the ribs in a few cases of empyema, and spoke of the necessity of preserving enough of the periosteum to cover the ends of the ribs, otherwise necrosis is apt to occur.

Dr. Charles H. Thomas said it is a question in his mind whether it is not best to *repeat* aspiration of the bladder; it may be done *once* in order to gain a few hours' time. He mentioned a case of ovarian tumor in which the aspirator was used; only a small quantity of fluid was drawn off. In a short time there was a rigor, and death occurred in three days. The autopsy revealed the evidences of peritonitis. Exploratory abdominal incisions should be considered, rather than aspiration.

Dr. Henry Hartshorne spoke of a case of empyæma in the medical ward of the Pennsylvania Hospital in the year 1840, in which spontaneous rupture occurred. The case terminated in recovery.

Dr. Stone, in closing the discussion, said that in children it was necessary to resect the ribs for empyæma, that they often recovered after simple withdrawal of the fluid.

Dr. John B. Roberts then gave a verbal report of a case in which

Imminent Death in Acute Pneumonia was Averted by Phlebotomy.

The patient was a man æt. 55. After exposure to cold pneumonia developed in the lower lobe of the left lung. One evening he was in great distress, respirations numbering 45 per minute. On percussion dullness and flatness were found over both lungs. On auscultation numerous coarse and some fine râles were heard on both sides. Lips cyanosed; death imminent. Dry cups were used over the chest posteriorly, and phlebotomy, to the extent of twelve ounces, practiced. The respirations immediately fell to 35 per minute. The patient became comparatively comfortable. Slept some during the night, and was much better the next morning. Convalescence went on uninterruptedly from that time.

Dr. Henry Hartshorne remarked upon the contrast between the now prevailing treatment of pneumonia, and other acute inflammatory affections, and that of forty years ago. Results do not show that the change has been to the advantage of medical practice. Formerly, even under hospital treatment, death from pneumonia was not frequent; in private practice it was rare.

Dr. L. P. Gebhard, near the end of half a century's large experience, said that he had never lost a case of uncomplicated pneumonia. Now we hear very different accounts. Men in the vigor of life not unfrequently die of the disease after a few days of illness.

Dr. Hartshorne has reached the conviction that a radical mistake is prevalent in regard to the practical indications in simple acute pneumonia. What have we therein as prominent pathological conditions? (1) Obstruction to the circulation at the seat of local inflammation. (2) Resulting general increase of vascular tension. (3) Arrest, or considerable diminution, of the secretions of the skin, kidneys, and bowels. In all these conditions there is no indication for alcohol, none for quinine, none for opium. The old-time remedy for the abnormal vascular tension of the first stage was the abstraction of a moderate amount of blood, according to the previous vigor of the patient, by venesection, cupping, or leeching. Having been brought up under this regime, Dr. Hartshorne can give personal testimony to its safety and frequent advantage. It is astonishing

that in these days of daring surgery, of ovariotomy, and laparotomy for various occasions, physicians should be so much afraid of taking from a patient a few ounces of blood. An adjuvant for such a measure of relief in the early stage of pneumonia, or substitute for it in doubtful cases, is the use of saline purgatives and diaphoretics. These, also, appear to be, in recent practice, very often, perhaps generally, neglected, Dr. Hartshorne believes, to a great disadvantage.

Frankly speaking, under the following plan of practice, six out of ten cases of acute pneumonia, in persons of previously good health, between 20 and 50 years of age, may be reasonably expected to die, viz., treating them, from the start, with twenty grains of quinine daily, a tablespoonful of whisky every two or three hours, and a quarter of a grain of sulphate of morphia every six or eight hours. If any patients recover under such treatment, it is an escape probably due to the use of large hot poultices kept applied to the chest; an excellent application.

Another method of treatment, Dr. Hartshorne has had ample experimental reason for believing, will be followed by recovery in at least eight out of ten cases of simple acute pneumonia in persons not over 60 years of age, of previously good health, viz., the abstraction on the first, second, or not later than the third day, of a few ounces of blood, from the arm in the stronger patients, by cups or leeches in those of less previous vigor of system; about the same time a decidedly purgative dose of some mild saline medicine; afterwards, every two or three hours, a saline diaphoretic, citrate, acetate, or nitrate of potassium, or acetate of ammonium; in the most violent cases, in patients of average constitution, tartar emetic during the first three, four, or five days, not more than one-sixteenth to one-twelfth of a grain every three or four hours, not allowed to cause gastric distress; a warm poultice, also, being kept applied and renewed over the whole anterior part of the chest, until the worst is over. Should this practice be just now out of fashion, it may be very earnestly said that it is better to be old-fashioned than to lose a lose a considerable number of patients, dying of a malady like pneumonia, which *ought not to be mortal.*

Whooping-cough Treated by Nasal Insufflations.

Dr. T. Guerder made the following communication at a recent meeting of the Society of Practical Medicine. In the beginning of last February an epidemic of a severe form of whooping-cough broke out at Pontcarré; infants were especially attacked. At first the disease was treated by fumigations of carbolic acid in the patients' rooms, and the administration of beliadonna, carbolic acid, and bromide of potassium, with syrup of poppies. The fits of coughing became less frequent, and the reflex excitability was favorably modified; but when the treatment was suspended, the cough assumed its original violence. On account of the extreme susceptibility of many of the children to belladonna poisoning, it was frequently necessary to discontinue the use of the syrup. In the case of a boy, aged 4 years, two teaspoonsfuls daily caused the pupils to dilate, and delirium ensued. Whooping-cough requires protracted treatment, and it was not advisable to administer narcotics to young children for several weeks, even when they could be tolerated. The presence of nasal catarrh, with congestion of the pituitary mucous membrane, and the probable parasitic nature of the complaint, suggested to Dr. Guerder the advisability of local treatment similar to that which had been successful in hay fever. The probability that fits of whooping-cough might be attributed to a nasal reflex action determined fits of coughing or attacks of asthma. Nasal insufflations were practiced with a very fine powder composed of boric acid and dried coffee in equal parts. The insufflations were effected by means of a form of nasal insufflator which scattered the powder whilst projecting it into the nostrils, and thus prevented any accumulation on a limited area of the mucous membrane. This detail was of importance, inasmuch as when the treatment was first adopted it was unsuccessful, because the mothers did not understand

now to effect the insufflation; but there was a marked improvement when it was performed night and morning by a physician. Thirty children were treated in this way; seven of them were scarcely a year old, seven were from one to two years old, six from two to three, and ten from three to eight. Among these thirty children, thirteen had been treated for a week or a fortnight with the syrup above mentioned, and a very decided improvement was noticed, but only of short duration. The remaining seventeen were exclusively treated with nasal insufflations, not taking any other medicine, excepting one or two emetics during the catarrhal period. Out of the thirteen children treated with syrup during the first period, from February 5 to February 10, three had attacks of intercurrent pneumonia; two children of 7 and 11 months succumbed, the other, 8 years old, recovered. It should be noted that, during the attack of pneumonia, the fits of coughing entirely subsided, but returned with the same violence during convalescence. From the day when nasal insufflations were employed, no further complications ensued, nor did any more deaths occur.

The new treatment was begun on February 19, with the boy, aged four, already referred to, who was unable to take belladonna, and who had fits of coughing every hour, night and day. At the end of forty-eight hours, and after four insufflations, the fits of coughing only occurred four times during the night, and five or six times in the day. When the treatment had been continued for a week, only one or two slight attacks of coughing came on during the twenty-four hours. With all the other children, the results were the same when the insufflations had been well performed. In a short space of time, varying from two days to a week, the fits of coughing generally diminished from twenty to fifteen, or even less, in twenty-four hours, and they grew less violent; vomiting and epistaxis also became less frequent. These results were simultaneous with the diminution of the coryza. In half the number of cases, it was observed that, after an improvement was obtained, further progress was slowly effected, but the cough did not thoroughly subside until a fortnight had elapsed. When timely medical aid was obtained, nasal insufflations were performed at the onset of the complaint during the catarrhal period. In these cases, the attack was comparatively slight, and there was complete recovery in about a week or fortnight, and sometimes sooner. In three cases especially, there was a positive abortive influence, and the cough was not periodical; it is possible that these were cases of simple catarrh; nevertheless, the children were in daily contact with others suffering from whooping-cough. Eighteen children had been treated with insufflations of boric acid and powdered coffee, when an article appeared by M. Grasset giving an account of an analogous treatment in whooping-cough adopted by Herr Michael, of Hamburg, who, after trying insufflations with various powders, preferred pulverized benzoin. The results he obtained were as successful as Dr. Guerder's. The latter then tested the value of pulverized benzoin; the success was equal to that resulting from the use of boric acid and powdered coffee, but recovery was slower. In conclusion it may be stated, with regard to the subject of Dr. Guerder's memoir, that the method of nasal insufflations constitutes a simple treatment, which has proved to result in one of the most efficacious and rapid cures for whooping-cough hitherto known. It seems better calculated than any other remedy to modify morbid conditions occurring in the complaint, such as vomiting, hemorrhage, and emaciation, as well as any other complication, such as pneumonia.

Illustrations of Exceptional Symptoms and Examples of Rare Forms of Disease.

Mr. Jonathan Hutchinson thus writes in the *Brit. Med. Jour.*, June 26:

CASE OF ASPHYXIA OF EXTREMITIES (RAYNAUD'S DISEASE): PATIENT A HEALTHY YOUNG LADY: SOME FACTS AS TO INHERITANCE.

Within a month of my having seen Miss. B., another example of this condition, in almost exactly the same degree of severity, came under my notice, which seemed to discredit some of my conjectures as to possible causation. In this instance, the patient was a young lady (Miss. W., aged 21), who had never suffered from any enfeebling illness, and in whom there was no proved inheritance of gout. It was known that her paternal grandfather had been much troubled by dying of his fingers, and that her father was so also to a slight extent. Her father, who was still living, had a very slow pulse, not more than 40, but he was otherwise in good health. The grand-parent referred to had been robust, and had lived to nearly 90, but the condition had clearly been such as to attract attention. Whether the liability to gout was wholly absent, I cannot feel sure. Her

mother knew nothing of it, but I had attended a sister of hers, an aunt of the patient, many years ago, for a severe form of acne tuberosum of the nose. This affection is very rare in women, and, probably, never occurs excepting when hereditary. In men it is often a consequence of free living, in association with gout. I must not, however, lay too much stress on this, since it cannot be held to prove more than that there was, on both sides, a probable inheritance of feeble circulation.

Miss W. was, when I saw her, aged 21, well grown, rather stout, and, excepting that she was too pale, she appeared to be in excellent health. She was a student at Cambridge, and lived, in all respects, like other people. Yet her fingers were habitually as livid as those of a corpse. It was not a cold morning when she called on me, yet her finger-nails were quite blue. Her hands were dusky, the lividity disappearing by degrees, from the fingers upwards, and being replaced by a dull red. On the backs of the hands were many of the ill-defined, dull, crimson blotches, like the spots on plaice. Her fingers and hands generally were a little swollen, and were thus rendered stiff and awkward. Her nails were all slightly rough, and showed conspicuous white spots. On the back of her right hand and wrist were a number of little spots, all about the size of a split pea, which had only appeared during the last fortnight. They were all scaly, and were too uniform for common psoriasis. There were a few like them on the other hand.

It appeared that nothing peculiar had been observed in the state of Miss W.'s hands, until, at the age of fourteen, she went to a boarding-school at York. Here she suffered much from cold, and her hands began to be dusky. Before that, she had suffered much from chilblains, and had noticed that her hands would die if put into cold water. Since they had become livid, she had suffered much, in cold weather, from deep cracks in the fingers, near to the nails. I did not examine Miss W.'s feet, but was told that they were nearly in the same state as the hands, but not so bad.

Miss W. had observed that she was very easily heated by exercise, and readily took cold. Nothing, she said, helped the circulation in her hands so much as walking. It was far better than lawn tennis, which often, although heating her, made her hands very blue. She was always most comfortable in hot weather, but found heated rooms oppressive. A muff kept her hands much warmer than gloves. Her pulse was soft and feeble, and did not count more than 64. It was more feeble at the right wrist than at the left. There were no signs of heart disease, but very deliberate action.

Miss W. had several brothers and sisters, who showed no peculiarity of circulation; but it was feared that one sister, much younger, was going to develop a similar condition.

Feeble Circulation and Flushing: Inherited Gout and Child-bearing as Possible Causes.

An interesting example of enfeebled circulation was offered in the case of Mrs. G., a lady aged twenty-five, who had been married four years, and borne three children. She inherited gout, and also, as she said, feebleness of heart. Her chief reason for consulting me was a painful and very annoying tendency to flush. She was vivacious, and fond of society, and said that she was obliged to abstain from dining out on account of her tendency to flush up crimson on the slightest provocation, or without any cause whatever. She assured me that it occurred to such an extent that every one noticed it. It was usually excited by some ridiculously inadequate emotion; a question being addressed to her, or the name of a friend being mentioned. With this tendency to flush scarlet over the whole face and ears, was associated extreme coldness of the extremities; her fingers became, as she described it, "like carrots," red and cold. Her feet were always chilly, but not so much so as her hands. I found her pulse very soft and compressible. She had never herself suffered from gout, and had never had chilblains. The symptoms of which she complained had been present, more or less, all her life, but had much increased of late. She loved warm weather, and never found it too hot.

Yaws and Frambœsia.

The *Med. Times*, August 7, says that the disease known as "yaws," "frambœsia," "pian," etc., and to which it has recently been proposed to give the name "polypapilloma tropicum," has been studied by Pontoppidan, the well-known Danish dermatologist, in a recent visit to the Lesser Antilles and the interior of San Domingo. From his brochure (kindly sent the reporter) we learn that he has observed it chiefly in the colored race, whites being almost invariably exempt, either from some race idiosyncrasy, or, as Pontoppidan is inclined to think,

rather from their superior cleanliness. Here the reporter differs from him, as he has observed this and similar affections among the colored citizens of Philadelphia, who are certainly of more cleanly habits than the average German.

Frambœsia is a local, contagious skin affection, occurring without perceptible general symptoms, which shows itself in the form of small papules rising under the skin. When these have reached the size of a split pea the epidermic covering is thrown off, and the lesions appear as small tumors covered with a yellowish crust, looking like dirty ivory counters or a round bit of cheese. When the crust is removed, a moist, reddish, but not ulcerating, raised patch is observed, resembling the mucous papule of syphilis; and when the lesions are situated about the genito-anal region the resemblance is very strong. If proliferation has been rapid, the tumors may become hypertrophied and assume a raspberry-like appearance.

Pontoppidan correctly draws attention to the fact overlooked by Fox, Duhring, and other writers, that the removal of the crusts does not leave an ulcer behind, but only a moist surface. The affection, in fact, is highly superficial, belonging rather to processes like psoriasis or lupus erythematosus than to the more destructive processes.

Examination of the microscopic appearances of the eruption, made, we believe, for the first time by our author, demonstrated the absence of any fungus like tricophyton or microsporon, either in the crusts or deeper. Below the layer of dried pus and epidermic cells was found a layer of granulation cells in no way distinctive. But in the largest and best-developed patches the papillary layer was well marked and usually intact, though the papillæ were flattened and the rete wasted and full of round cells. The corium was everywhere normal. Though perhaps hyperæmic and succulent, it contained no foreign elements. The disease, therefore, in all probability, is situated in the rete Malpighii. The affection, though almost certainly contagious, must continue until the character of the contagion is made out to be classed among the neoplasmata. Pontoppidan prefers to call it yaws.

The Therapeutic Action of Chloride of Sodium.

After dealing with the physical and chemical properties of this salt, and its physiological action on animals and plants, Dr. Branche gives the results of his own observations in man. The blood, the saliva, and the urine show a notable increase in the proportion of the salt a few minutes after its ingestion. Its effect on digestion is not only to augment the secretion of gastric juice, but also to increase its acidity. After taking ten grammes daily, more than the usual quantity, for two months, the number of blood corpuscles was found to have increased, with a diminution of the albumen and watery constituents of the blood. The excretion of urea is increased, either owing to better diffusion or to acceleration of organic combustion. With ten grammes daily in addition to the ordinary consumption of salt, the amount of urea was augmented to the extent of four grammes (Rabuteau). Although certain advantages appear to follow a slight increase in the quantity of salt taken, an excess is certainly injurious; in one case death followed the ingestion of 500 grammes of sea-salt. This toxic effect, however, has been denied. Deprivation of the ordinary ration of salt is rapidly followed by general feebleness, albuminuria, and anæmia. The condition likely to derive most benefit from a course of treatment with chloride of sodium is (according to Dr. Branche) struma, but anæmia and tuberculosis are also improved, if not cured. Dr. Pidoux recommends phthisical patients to eat largely of salt at meals. Goat's milk, rendered saline by the addition of twelve to fifty grammes of salt to the diet of the animal daily, is highly spoken of. Bouchardat has remarked that well-salted meat diminishes the thirst of diabetic patients to some extent, and lessens the excretion of sugar. In the form of baths, its good results are well known in the treatment of chronic rheumatism, gout, gravel, and biliary calculi. Several observers have seen malarial fever arrested by doses of salt varying from ten to fifteen grammes. In solution, it has been recommended for intravenous injection for cholera, and to destroy the oxyuris vermicularis in children. The effect of salt is antidotal to nux vomica and curare, and to lead and silver salts. The necessity for avoiding the ingestion of salt in any form for some hours after the administration of calomel is, or should be, well known. In conclusion, Dr. Branche points out the benefit to be derived from the use of mineral waters of the Friederichshall type, containing chloride of sodium, whereby the depressing effect of saline laxatives is counteracted by the salt.

Case of Poisoning by Chloroform.

Dr. J. G. U. West thus writes in the *Lancet*, July 3:

On April 6, at 7 p. m., I was hastily summoned to a man aged fifty, a cab-driver, who had been found in his bedroom in an unconscious state. His wife had recently drowned herself, and at the inquest the jury had severely censured him for alleged ill-treatment of her. I found him lying on a bed in a state of deep coma; pupils slightly contracted, and not acting to light; breathing stertorous; complete muscular relaxation; conjunctivæ insensible to touch; pulse 96, regular, but very small. On smelling his breath, I detected a very strong odor of chloroform. There was no empty bottle in the room. I at once used the stomach-pump, obtaining four ounces of dark-brown fluid, which did not smell of chloroform. Up to this time I could get no history, but I now discovered that three hours before I saw him he came home from the direction of his stable, and went straight up-stairs. I sent a policeman to the stable, where he found an empty bottle labelled chloroform. The coma deepening, the breathing becoming shallower and more stertorous, and the pulse weaker and more frequent, I thought an antidote was essential, but I could find no allusion to poison by chloroform in any book in my possession. Assuming that the great danger was from failure of the heart's action, I thought that atropine would most probably prevent the cardio-inhibitory effect of the chloroform. As he was quite unable to swallow, I injected three-quarters of a grain of sulphate of atropia under the skin of the arm at 9 p. m. In twenty minutes the pupils began to dilate, and he moved his arms. The pulse improved, and the breathing lost its stertor. About midnight the conjunctivæ were sensitive to the touch, and at 3 a. m. on the following morning he became conscious and spoke. From this time he contiuued to improve, though for a few days he suffered from gastro-intestinal catarrh. He confessed that he bought two ounces of chloroform, saying that he wanted it to clean some clothes, that he drank it at the stable without diluting it, and then walked home, a distance of about 250 yards.

Whilst anxious to avoid the *post hoc propter hoc* fallacy, I think the case worthy of record as showing the probability of atropine and chloroform being antagonistic, and the fact of the patient exhibiting no sign of belladonna poisoning after the injection, appears to strengthen this hypothesis.

Valvular Heart Disease.

The old, erroneous idea that valvular heart disease meant the death-warrant of the person so afflicted, is happily discarded in the greater light of to-day. Sir Dyce Duckworth, M. D., contributes a paper on the subject to the *Brit. Med. Jour.* (July 3–10), in the course of which the following occurs:

"To sum up the whole question we have been considering, and to bring this very imperfect sketch of the subject to a close, I may remark that a diligent search amongst cases of cardiac valvulitis appears to bring out the fact that a favorable prognosis for many of them may be given. Certain valvular lesions have their special perils, and these pertain to certain individuals more than to others. At some epochs of life, too, the prognosis is graver than at others. In each case, however, the great point is to determine the personal factors which promise longevity or immunity from cardiac failure. As Corvisart put it: 'C'est apres la constitution de l'individu, son genre de vie . . . . qu'il pourra prononcer sur le terme fatal.' (*Op. cit.* p. 408.) And this question, indeed, meets us, I believe, in every case of disease we are called to treat. What does this malady mean in this individual? What will it do for him, and how will he bear it? The great law of compensation is now well understood to be the protecting agency in all these cases. So long as nutrition is well maintained, and a regular, prudent, and equable life is lived, so long will cardiac valvular lesions fail to give rise to serious symptoms. Dr. Semple has the credit of having called attention, thirty-six years ago, to the fact that many persons reached advanced age although suffering from heart disease, many of them being quite unconscious that they were the subjects of it. (*Op. cit.*, p. 104.) What we have to try to discover are the conditions which render tolerable the lives of persons so suffering. The lesions of each valve affected require a special study. The question how far compensating changes behind the valves can be met, must be answered in the case of each valve, and in respect of the textural habit of each patient. Discrepancies occur in the opinions given as to the relative gravity of the different forms of valvular disease."

A Case of Intussusception, with Sloughing and Discharge of a Large Piece of Intestine, followed by Recovery.

Dr. J. G. Porteous thus writes in *Gaillard's Medical Journal:*

B——, a school-boy, thirteen years of age, while suffering, in May, 1885, from a severe attack of diarrhœa, was suddenly seized with severe pain in abdomen, vomit-

ing, and entire cessation of the diarrhœa, although there was a constant desire to go to stool and severe tenesmus.

I found him a few hours after with the abdomen swollen and tender, and the indications of a tumor to the left of the umbilicus. Having made the diagnosis of intussusception, I injected two quarts of warm water through a rectal tube, and this was followed by a small dejection accompanied with some blood. The tumor then disappeared, and the vomiting soon stopped. Next I gave a spoonful of castor oil with ten minims of laudanum, which was followed by a free evacuation and entire relief. The boy remained weak through the summer, with a tendency to pain and soreness of the bowels.

On the 15th of May last, after violent exertion in playing base ball, he was taken with severe vomiting and moderate pain in the abdomen. On the 16th a cathartic was given, which increased the pain but did not cause a movement. On the 17th some small powders of morphine and bismuth were given, which partially controlled the vomiting and pain. An injection of a pint and a half of warm water produced no effect.

May 18. Abdomen swollen and tympanitic. No distinct tumor, but some tumefaction, with a feeling of hardness to the left of the umbilicus. I gave two large injections, and after the second there was a moderate passage. I then gave oil and laudanum, which was followed by several copious evacuations, with some blood. The vomiting ceased, but some pain and soreness remained. After that the bowels moved naturally every day until the 28th. On the 29th the patient had a convulsion, and after an enema of a pint of water there was a moderate evacuation, which was accompanied by the piece of *intestine* now presented. He required some assistance in passing the last half.

The boy is now doing well. He has a good appetite, and his bowels are regular; and with the exception of a slight tenderness in the left side of the abdomen, he makes no complaint. The piece of intestine measures a little over seven inches in length.

Operative Treatment of Traumatic Stricture.

In a paper on Retrograde Catheterism first published in the *Gazette Médicale de Nantes*, and recently reprinted in the form of a pamphlet, Dr. Poisson insists on the necessity of performing primary external urethrotomy in cases of serious rupture of the perineum from a fall on to the perineum. In such cases, Professor Guyon holds, an immediate perineal incision, freely made, and extending to the injured portion of the urethra, is strongly indicated, and is as much an operation of necessity as kelotomy and tracheotomy. A catheter may sometimes be guided along the whole length of the divided urethra into the bladder; but, though the surgeon may fail in doing this through the perineal wound, he will by this incision remove all risks attending infiltration of urine. When it is too late to act thus, and the urethra has become impermeable, and immediate operative interference is necessitated by retention, hypogastric puncture of the bladder will remove all urgent symptoms, and favor an early restoration of the patency of the canal. In practicing retrograde catheterism it is necessary to have a solution of continuity behind the seat of urethral obstruction. Of the two methods of establishing this solution of continuity; namely, suprapubic cystotomy and hypogastric puncture, the latter, M. Poisson argues, is preferable, and well adapted to the conditions of the case, being sufficient for the ready practicing of retrograde catheterism, and presenting much less risk than the major operation. By the simple proceeding of hypogastric puncture, the inflammatory condition of the injured portion of urethra may be much relieved, and possibly the canal, in the course of a few days, may be traversed by a small instrument passed by the outer meatus. In any case, under the influence of the puncture, the general condition of the patient is improved, the severe suffering of retention is relieved, and necessary time is gained for taking into consideration the re-establishment of the urethra, facilitated by the presence of a vesical fistula. In conclusion, Dr. Poisson states that retrograde catheterism, often necessary to the due completion of external urethrotomy, may be readily carried out by a hypogastric fistula, and that, in every case where it is possible, puncture should be preferred to the more dangerous operation of suprapubic section.

—In the *Edinburgh Med. Jour.* for August Dr. Byron Bramwell reports a case of aneurism of the right internal carotid artery. Rupture; convulsion; violent delirium, followed by pain in the back of the head, stiffness of the neck, and retraction of the head. Second rupture a fortnight after the first attack; convulsions, delirium; coma; rapid rise of temperature; death.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

THE INTERNATIONAL MEDICAL CONGRESS.

Is it not preposterous for the *Medical Record* and those whom it represents, is it not even more than preposterous, is it not audacious, for it and them to pretend for one minute that the coming International Medical Congress will not be graced by the presence of great men, men of world-wide reputation, men who care not for the personal bickerings of the disappointed, but who recognize in this Congress a great scientific opportunity for learning and teaching?

From the *London Lancet* (certainly an impartial source) we draw the information that such distinguished men as Drs. B. W. Richardson and Thudichum have accepted the positions of Vice-Presidents of the Section of Public and International Hygiene, and Mr. Simon will probably accept a similar position. The *Lancet* also goes on to say:

"We are glad to be able to report a very general desire among leaders in London to be present at Washington in 1887. Whatever hesitation they felt some time ago in view of the divided state of feeling in America is now steadily giving place to a desire for the success of the Congress, and a wish to do anything they can to further it. We feel quite justified in saying that our best men in England and Scotland are preparing to go, if they get any indication that their presence will be acceptable. Sir James Paget, Sir Andrew Clark, Sir Spencer Wells, Professor John Chiene, Professor Fraser, and we believe Sir William Turner, are all, according to our information, likely to go.

"It is not America alone that is interested in the success of the meeting at Washington, but the profession throughout the whole world, and we might add the world itself. When our profession meets internationally, it is of good omen. We not only stimulate fraternity and scientific rivalry amongst ourselves, but every thought in advance and every medical discovery is a great boon for the human race and for all nations. We urge on members of our profession in the empire to strain a point to be at Washington on or before September, 1887, where, if report is to be trusted, a very hospitable reception awaits them."

Does this look as though the Congress was destined to be the failure that the *Medical Record*, the *Medical News*, and some similar aristocratic journals, would have wished?

Not much! The great medical men of Europe would, of course, be glad to meet the great medical men of this country—that is *all* of them; but they have too much good sense to stay away from a scientific gathering, to

miss the opportunity of seeing and knowing the profession of America, because a few disappointed men wish them to do so. They will come, they will be royally welcomed and entertained, and when they ask *certain editors,* with surprise depicted on their countenances, how they could ever have said that such a glorious gathering as this will be was doomed to a dismal failure, or even (think of it) not to be at all, we will be behind the door to hear what answer will be made.

Our foreign friends were well acquainted with the late Professor Austin Flint, and they regarded him very highly; and when they found that the Congress was good enough for him, they sensibly concluded that it was also good enough for them, notwithstanding the outcry of a disappointed clique.

LOOK OUT FOR YOUR REPUTATION.

"*Out of sight is out of mind.*" It is one of the duties of journalism to give advice, no matter how thanklessly it may be received. Reputation is a precarious thing, and unless carefully guarded is very apt to take wings and fly away.

In what does reputation consist? Essentially in hearing of and seeing a man or his name in good company, associated with some work that is calculated to benefit the world in which he lives. He may be so engaged, but if such fact is not made public he fails to secure reputation. Well, then, there are certain medical gentlemen in this country who have been for years actively and honorably engaged in furthering the standard of their profession and conferring benefit upon humanity.

In so doing their names have become familiar medical household words; they have achieved reputations; they are honored and respected everywhere. But now they are like "*Mary in the dumps*"—they are sulky, and say that they will not attend our International Congress. For their own sakes, we advise them to reconsider this determination. There are others who have done most excellent work, but who have not yet attained the exalted reputation enjoyed by those of whom we speak. They will be present at the Congress, and they will take their best work there, and when our foreign visitors hear, see, and know them, they will be very apt to conclude that as we are a fast-living people, the race of leaders of American medicine with whom they have hitherto been familiar has run its course, and has been succeeded by the class of men whom they meet at the Congress, whom they will find fully worthy of being considered leaders.

This hint is thrown out that those who have won great repututions by dint of hard and honest labor may not foolishly throw them away to gratify an unreasonable and unreasoning spite.

"*Do not cut off your nose to spite your face.*"

AMERICAN PUBLIC HEALTH ASSOCIATION.

The meeting of this association this year will be held in Toronto, October 4 to 8. It is expected that this will be the greatest meeting in the history of the association, as there will be not only a very large attendance from this country, but many distinguished sanitarians from abroad will be on hand. The Annual Conference of State Board of Health will be held during this meeting.

THE BRITISH MEDICAL ASSOCIATION.

The 54th annual meeting of this association, which was held in Brighton on August 10, 11, 12, and 13, was one of unusual interest. The papers read were of a particularly valuable character, and we shall take occasion to place the essence of them before our readers from time to time in the various departments of the REPORTER.

NOTES AND COMMENTS.

Rheumatism in Children.

It is a dismal fact that a very large number of the cardiac affections of adult life are directly traceable to but imperfectly appreciated attacks of rheumatism in early life. Dr. Angel Money, writing on this subject in the *Lancet* (July 24), says that the rheumatism of children is one of the most hopeful affections that the medical man could have to treat, provided that the diagnosis be made at an early stage of its development—a very large proviso. But the affection might be easily overlooked on account of the slightness of the subjective symptoms. How important was it that a most careful physical examination should be made in all cases of even slight ailments. Some of the rheumatism of children was so insidious in its operation, that it was conceivable for the disease to be at work without giving signs either of a subjective or an objective order.

A child who has any sign of rheumatism about it should be kept absolutely all day

and night in bed. Even if a mere urticaria or erythema be the only sign to be found, the bed should be tried for a day or two and the case watched for other members of the rheumatic series. Whilst holding that erythemata, the nodules, periarthritis, chorea, and heart disease were perhaps most frequently of rheumatic origin in children, Dr. Money allowed fully that any of these symptoms might own several other causes. Not all erythemata and chorea are rheumatic, nor is all periarthritis and endocarditis of rheumatic origin.

As to the further treatment the principles are of the simplest order, but at the bedside many details have to be borne in mind, and must be acquired by the practitioner himself, for no amount of lecturing could impart the necessities of treatment of any individual case. Dr. Money has faith in the employment of moderate quantities of bland fluids, like barley-water or toast-and-water, to which might be added the alkaline carbonates, the effects of which were probably, he suggested, enhanced by their administration in dilute form. Salicylate of soda or salicine was of value in some cases of rheumatism in children, but in his experience of less value than in adults, whose pain and joint affection were so much more a part of their suffering.

Neuralgia of the Pudic Nerve.

Professor Adamkiewicz mentions in the Polish journal *Medycyna* a somewhat rare case of neuralgia affecting the pudic nerve. The neuralgias of the ovary and uterus in women and of the seminal ducts in men are, he says, usually described as neuralgiæ pudendo-hæmorrhoidales, but they have not been well worked out. The present case is interesting because the nerve affected arises from the pelvic plexus. Three years ago the patient began to suffer two months after her second confinement with painful spasm of the urethra whenever she attempted to micturate; sometimes, indeed, this spasm prevented her from voiding her urine. Afterwards the pain spread to the vesical region, and became more and more frequent, so that at last the woman was scarceely ever free from it. Every movement of the body, and any irritation or excitement, increased it, and induced a desire to micturate. Morphia and absolute rest in bed produced some alleviation only. A painful spot was found where the gluteus maximus crosses the tuberosity of the ischium, and another on the inner surface of the ascending ramus of the ischium. The treatment adopted was electrical, the anode of a constant current battery being placed between the tuberosity and the spine of the ischium, and the cathode on the sacrum. After daily applications of a few minutes' duration for three months, the patient was completely cured.

Progressive Facial Hemiatrophy.

A girl of nineteen is mentioned in the reports of the Swedish Medical Society as having suffered from the above-mentioned disease for four years. The first symptom was continuous but not severe headache, situated in the right temple, cheek-bone, and crown of the head. After three years she noticed a contortion in her face, with depression of the right temple and cheek-bone. On close examination, Dr. Wärfvinge discovered that the right half of the face from the temporal region to the lower jaw was extremely atrophied, the atrophy affecting the skin, mucous membrane, muscles, fat, and bone. The muscles, however, were not completely atrophied, since they contracted at will or by faradization. The skin of the atrophied parts could be lifted up in thin folds. The sensibility on the right side of the face was normal, and there was never any sensation of creeping or cold. There was no disturbance in the circulation of the blood; no abnormal dryness or humidity; no spots on the affected side. The color was the same on both sides; the hair on the right temple a little thinner than on the left. The tongue was found to be thinner on one side than the other, but the taste on both sides was the same. The organs of sight, hearing, and smell presented nothing remarkable.

Soft Chancre of the Middle Ear.

The *Gaseta Lekarska*, a Polish medical journal, contains a report by Dr. Guranowski of a case of soft chancre of the middle ear. The patient was a woman with a phagedænic chancre of the genitals, who from snuffing tobacco managed to introduce the virus into the nose, where the septum had become ulcerated, with copious discharge of foul pus. From this the infective material must have passed through the Eustachian tube into the middle ear. Deafness and pain were complained of, and subsequently perforation of the tympanic membrane occurred, a large quantity of purulent matter being discharged through the opening and infecting in its turn the external meatus. The case was treated by the introduction of iodoform into

the ear and nose, and by injecting warm water through the ear by means of the Eustachian catheter. In a month's time the patient regained her power of hearing and completely recovered. Dr. Guranowski has a great belief in the efficacy of washing the middle ear with warm water, having seen cases of severe inflammation recover under this treatment where it was feared that the only hope of saving the patient's life lay in trephining the mastoid process.

Permanent Closure of the Orbital Cavity.

After the removal of the eyeball, there are many reasons why it is desirable to permanently close the orbital cavity—that is in those who, for some reason or other, do not mean to use an artificial eye. Therefore it is we note that before an English medical society Dr. Edwyn Andrew exhibited a man on whom he had performed his operation for permanently closing the orbital cavity, after excision of the eyeball, by removing all the ocular and palpebral mucous membrane, the cartilages, and edges of the lids, and allowing the cut surfaces to unite. He pointed out the great advantages of this operation for the artisan class; no dirty discharging socket was left, and it rendered the person quite independent of the weather, or of the dirty surroundings of his occupation, enabled him to dispense with a shade, or any other covering, and saved the expense of an artificial eye, which, if not frequently renewed, became a great evil. He mentioned also that this was one of many cases which showed that the fear of a lachrymal fistula from such an operation was quite erroneous, for probably the lachrymal gland, not being stimulated to action, wasted away.

Radical Cure of Hernia by a Bubo.

"It is an ill wind that blows nobody good," is a very old and very true saying. If buboes are going to radically cure herniæ, then we must look with a little more respect upon the chancroid, or whatever it is that causes the bubo. That the bubo has thus acted conservatively in at least one case, is evidenced by the fact that Dr. F. B. Streeter, of Glens Falls, N. Y., reports the following case to the *Medical Record:* "H——, aged 34 years, Irish-American, canal-boat captain by occupation, while loading his boat in the summer of 1882, sustained a severe strain, which resulted in a direct inguinal hernia of the left side. It was easily reduced and retained by a truss. In the summer of 1883 he again consulted me, this time for a bubo on the same side. After a long period of extensive inflammation with suppuration, during which he was unable to wear a truss, he recovered from his bubo, and from his hernia as well. Up to the present time his hernia has not recurred, although he is engaged in the heaviest labor. A suitable case presenting itself, I propose to try the effect of vaccination, although I hardly expect to gain results equal to those obtained by the 'bubo' treatment."

A Curative for Epithelioma.

It is not condurango this time, but salicylic acid and the inevitable, ever-present cocaine. So writes Dr. D. Tod Gilliam, of Columbus, Ohio, to the *Medical Record:* "It so happened, (he says) not long since, that I had a small epithelial growth to remove from the face, and resorted to a 20-grain solution of cocaine as a local anæsthetic. After a lapse of some minutes I was surprised to find the diseased parts not only exsanguined, as is usually the case after the use of cocaine, but extremely friable and crumbly. I saturated a good-sized pledget of absorbent cotton with the cocaine and reapplied it, leaving it on for about thirty minutes. At the expiration of that time the diseased mass fell away with the slightest touch of the curette, leaving a healthy-looking surface, which has healed kindly. This, I dare say, was not an epithelioma in the sense of being malignant, but was undoubtedly epithelial in character, and has suggested to me the feasibility of using cocaine in the former class of cases." Dr. G.'s suggestion is certainly well worthy of trial.

Gaseous Medication per Rectum.

The ingestion of gaseous medicines by the lower bowel was the subject of a recent communication by M. L. Bergeon to the Paris Academy of Sciences (*Comptes Rendus,* July 12th). His research has extended to a variety of diseases, but for the present he only records his experience in the treatment of pulmonary phthisis. After having tried a variety of balsamic substances of parasiticide or antiseptic repute, M. Bergeon gave the preference to sulphurous mineral waters (Eaux Bonnes, Challes, etc.). A current of from four to five litres of carbonic acid gas traversing from 250 to 500 grammes of the sulphurous mineral water was introduced per rectum twice in the twenty-four hours. After a few days' use, cough was notably diminished and almost suppressed, the expec-

toration greatly modified in quality and quantity, the sweating stopped, and the general state improved; and that not only in incipient, but also in confirmed phthisis. Daily auscultation established the disappearance of moist râles.

Ligature of the Brachial Artery for Cellulitis.

An interesting case of extensive cellulitis of the arm cured by ligature of the brachial artery was related by Dr. F. H. Gross at a recent meeting of the Philadelphia Surgical Society. The patient was a man who had been kicked by a horse, the middle finger having been injured as a result of the accident. In spite of treatment by an apothecary, the condition of the part continued to become more serious, and a surgeon was called in to treat the case, cellulitis being then established, and the arm greatly swelled and excessively painful. Rigors, fevers, and delirium set in, and an abscess formed in the region of the wrist, from which point also violent hemorrhage occurred. Ligature of the radial artery failed to arrest this bleeding, which was then thought to arise from the anterior interosseous vessel, and Esmarch's bandage being applied, the man was sent into hospital. All this time the arm preserved its hugely swollen condition, and presented the appearance of incipient gangrene when seen by Dr. Gross, who at once proceeded to tie the brachial. Within twelve hours of the operation the cellulitis below the seat of ligature had entirely melted away, while concurrently an abscess formed above, and opened into the incision made for the application of the ligature.

Recovery of the Chronic Insane.

Dr. P. M. Wise, Superintendent of the Willard Asylum for the Insane, writing on this subject, says that it is certainly not safe to predict incurability in any case where secondary weakness has not progressed to impotency. He quoted one case in which deep dementia following a fifth attack of mania was recovered from in the course of a week, the patient having been insane for nine years. The writer also gives three instances in which convalescence from typhoid fever was accompanied by recovery from insanity of one, two and a half, and three years' standing. The menopause in one of his cases put an end to violent and destructive mania of about six years' standing. In two instances, an acute maniacal attack breaking in upon dementia and chronic mania is shown to have been the first definite step towards recovery; and in one case, that of a boy sixteen years of age, an unsuccessful attempt at suicide "appeared to be the crisis of his alienation, and thenceforward he improved rapidly and recovered."

Hemorrhage after Tonsillotomy.

While not, as a rule, severe, yet it does occasionally happen that alarming hemorrhage occurs after this operation. Dr. J. Walker Downie relates several such cases in the *Edinburgh Med. Jour.* for August, and concludes by saying:

"Following the removal of the desired portion of the hypertrophied tonsil, sipping cold water, or better, the tanno-gallic acid gargle of the London Throat Hospital Pharmacopœia, slowly sipped, is sufficient to quickly check any bleeding which is present in ordinary cases. The latter can be relied on to check even comparatively smart hemorrhage. Should this fail, however, the part should be well swabbed with strong perchloride of iron solution—accompanied, possibly, with its administration internally at *short* intervals—and should even this be without effect in checking it, I personally should now never dream of trying other styptics, but should at once, in those very exceptional cases, have resort to the actual cautery."

Treatment of Somnambulism.

It is not often that we find somnambulism treated of in medical journals, but we can readily conceive how this condition will, not infrequently, call for relief from the physician. Dr. J. W. Keene has a very good article on the subject in the *Medical Press of Western New York* for August, wherein, speaking of treatment, he says that there is little to be said, except that somnambulism should be recognized as a disease, or, at least, a symptom of disease, and treated according to causation, when that can be ascertained. Efforts to break up the habit should be made. Punishment, drenching with water, etc., are contraindicated. Dr. Hammond extols the bromide of potassium. Iron, quinine, strychnia, and phosphorus may be exhibited with advantage, according to special indications. These remedies, together with proper hygiene, both physical and mental, seldom fail to benefit the patient, if not to effect a cure.

Warm Ether as an Anæsthetic.

Dr. M. W. Hobbs advocates in the Cincinnati *Lancet-Clinic* the advantage of warm-

ing ether previous to its administration in the production of anæsthesia. He uses a special form of inhaler, in which the ether is warmed by being placed in a chamber surrounded by hot water, and the vapor is mixed with a certain proportion of air before being inhaled. He finds that anæsthesia is produced more rapidly, and with the expenditure of less ether, than when the agent is used cold. He and Dr. Taylor have tried the method in upwards of thirty cases, and he writes that the patients not only came under the influence of the drug more readily, but they also recovered more rapidly and pleasantly from the anæsthesia than patients generally do who have been brought under its influence in the ordinary way of administering ether cold.

Avulsion of Scrotum.

Before an English medical society, Dr. Ratton related a case in which the scrotum, together with the skin of the penis, were torn off by revolving rollers, leaving the penis, testicles, and the perineum as far as the anus, denuded. There was little bleeding, and the testicles were not even tender. The wound showed a tendency to heal well under corrosive sublimate and boracic dressings. Dr. Ratton pointed out that the scrotum came away precisely in the lines of the incision employed for the removal of the elephantoid scrotum. The steps of the operation were, however, reversed; for, in the accident, the scrotum was first removed. He discussed the question whether there would be any advantage in performing the operation in this reversed method, but decided in the negative.

Congenital Deformity of Forearms.

Before an English medical society, Dr. Evans showed a boy, aged 16, with congenitally deformed forearms. The right forearm and elbow were ankylosed and semiflexed at an angle of 120°, and the forearm was in a position midway between supination and pronation. The head of the radius appeared to be dislocated forwards; the radius measured four and a half inches, and was non-rotatory; the ulna was six inches long. The wrist-joint was normal, but the hand was a little abducted. The left forearm and elbow were movable; the ulna measured three and three-quarters inches in length; the radius, about two inches long, did not appear to reach the humerus. No supinatory or pronatory movements were possible. The patient had also genu valgum in both legs.

Statistics Relating to Operations on the Kidney.

Dr. David Newman, of the Royal Infirmary, Glasgow, having collected, with a view to publication, the statistics relating to operations on the kidney for the relief of disease, is desirous of receiving from surgeons, whose operations of the kind have not been recorded, a statement of such cases. For this purpose a schedule has been prepared, a copy of which, Dr. Newman asks us to state, will be forwarded to any surgeon who may apply to him. The schedule, which contains columns headed "Diseased condition as ultimately determined," and "Results—immediate and ultimate," has already been sent to those operators whose cases have been published, in order that the records of them may be thoroughly authenticated and rendered complete.

Operation for Rectal Cancer.

Dr. Arturo Guarneri relates, in the *Gazzetta degli Ospitali* of July 14th, a case from Volkmann's clinique, illustrating very forcibly the modern practice of attacking cancer of the rectum with the knife. The patient, a single woman, aged twenty, had undergone extirpation of the rectum for epithelioma. The disease having returned, some more of the intestine was removed, with a large portion of skin, part of the vaginal wall, and a piece of the ischiatic tuberosity. The peritoneum was opened; nevertheless the patient recovered almost perfectly, and a plastic operation was subsequently performed to shut off the vagina and reconstruct the perineum. A detailed history of the procedure and of the final issue could not fail to be instructive.

Numerous Intestinal Perforations in an Habitual Drinker.

Dr. Palmer, of Batavia, sends to the *Medical Press of Western New York* a brief note concerning a patient, whom he had long known as an habitual drinker, who complained one afternoon of abdominal pain, for which he prescribed, and whom he found dying at ten o'clock the same evening.

On autopsy it was discovered that there had been severe enteritis with ulceration; several ulcers, being of sizes from a millet seed up to that of a split pea, had given way, and as a result there were numerous perforations with escape of fœcal matter and speedy collapse and death.

Such a number of perforations within so short a length of intestine makes the case quite peculiar.

Warm Baths in Scarlatina.

The London *Lancet* has an article on the use of warm baths in scarlatina, in which the author says that he has pursued this practice for fifteen years and has never lost a patient from the disease. He orders his patient to have warm baths daily, to be kept in from three to five minutes, rapidly dried, wrapped in a blanket, and returned to bed. He observes, first, that it brings out the rash; second, that it reduces the temperature; third, that it soothes the patient, promoting rest in nervous cases.

To this experience Dr. E. B. Montgomery, of Quincy, Ill. (*Progress* for August), adds his own as to the use of warm baths in scarlatina, particularly in two cases beginning with severe convulsions. In both cases warm baths were used four or five times a day for several days with the happiest effects, both cases recovering.

Unusual Effects of Morphia.

Either that some persons possess an unusual susceptibility to morphia, or that some druggists do not prepare the drug properly, or possess scales that are not accurate, seems evident from the numerous peculiar cases that are reported. The last instance of this kind we find in the *Brit. Med. Jour.*, July 10, wherein a correspondent says that a young woman, aged about 25, pale but healthy, had acute neuralgia of the face, for which she had a quarter of a grain of morphine injected hypodermically (three minims of Tarnier's permanent solution of morphine with atropine). She began to sleep, and became comatose, with stertorous respiration. Such cases warn us to be extremely careful with this drug.

Ingrowing Toe-Nail.

For ingrowing toe-nail, M. Lucas-Championnière recommends washing the toe with a five per cent. solution of carbolic acid. Local anæsthesia is produced, the nail is removed by avulsion, and the rim of the bed of the nail is excised. Carbolic acid is again used, and a salicylic cotton-wool dressing impregnated with vaseline, containing a fifth of boric acid, is applied; it is then powdered over with iodoform, and enveloped in salicylic cotton-wool, which is again enveloped in ordinary cotton-wool, and finally bandaged. After an interval of three weeks, there is cicatrization, and the dressing is removed.

Linseed Oil in Pruritus Ani.

A correspondent writes to the *Boston M. and S. Jour.* that he has lately witnessed the triumph of linseed oil in the treatment of pruritus ani where all the classical remedies had failed. In the case of two patients who had been for several years sufferers from pruritus ani with a trifling erythematous eruption and no rectal complications that could be discovered, the free external use of linseed oil at bed time about the parts gave immediate relief, and thus far free inunction with this simple remedy has given complete exemption from nocturnal annoyance.

The Treatment of Carbuncle.

Carbolic acid has been already recommended for the cure of this trouble, but usually it is recommended to inject the drug pure and simple. Now, Dr. Norman Gay, of Columbus, Ohio, in the *Columbus Medical Jour.* for August, advises us to use the acid and olive oil (one to seven), which he injects (a few drops) into the boggy part of the sore, after which he applies lint, wet with carbolic acid, olive oil and chloroform, of each equal parts. The oil does not seem to lessen the good effects of the acid, while it renders the injection much safer.

Temporary Dilatation of the Heart in Acute Disease.

It would seem as though we were to find, in this condition, an explanation of some of the hitherto unaccountable sudden deaths in acute disease, for in the *Practitioner* for July Dr. G. Coates says that though he has no data as to the relative frequency with which simple dilatation of the heart takes place in acute disease, yet he believes it probable that it is fairly frequent, and that much light would be thrown upon the nature of collapse in acute disease if, in all cases, the size of the heart was carefully determined from day to day.

A Strange Tampon.

A writer in the *Deutsche Medicinal Zeitung* states that he was called to see a peasant woman in the country who was suffering from hemorrhage from the genital organs. When he arrived he found her vagina filled with fresh horse manure, and the external genitals plastered over with the same material. The patient insisted that she wanted only some medicine, and would not permit the removal of the tampon. She shortly afterward had an attack of septicæmia.

The Function of the Tonsils.

Dr. R. Hingston Fox, in an interesting article on the Functions of the Tonsils in the twentieth volume of the *Journal of Anatomy and Physiology*, expresses the opinion that those glands belong to the digestive and not the respiratory tract, and that their function is to reabsorb certain constituents of the saliva in the intervals of meals, which would otherwise be wasted. He thinks that the view of their having an absorbing function is further supported by the strong evidence of the power of the tonsils to absorb morbid poisons directly from the saliva.

Hydatid of the Lung Producing no Symptoms.

A specimen of hydatid cyst of the lung was shown at a recent meeting of the Paris Anatomical Society by M. Limpéropoulo. It was situated in the parenchyma, and was about the size of a large nut, the wall being thick and containing calcareous granules. No symptom of this foreign body's existence in the lung was observed during life, beyond some chronic bronchitis and emphysema from which the patient suffered. There were, besides, cardiac hypertrophy and interstitial nephritis.

Internal Hemorrhoids.

As it is not always an easy matter to bring internal hemorrhoids into view, we should be always aware of what might be termed "the little devices of surgery." In the *Brit. Med. Jour.* (July 31), Dr. F. A. A. Smith tells us that he uses a piece of hard wood, shaped something like the plug of a female speculum. The shoulder should be slightly cupped inside. When oiled, it is easily inserted into the rectum, and, on withdrawal, causes all internal piles to protrude.

Heart Disease and Consumption.

Some authors say with *heart disease* there is no consumption, but Prof. DaCosta recently showed the class at the Pennsylvania Hospital a bad case of phthisis, with cavities and the bacillus tuberculosis in the sputum, and at the same time aortic regurgitation of fifteen years' standing and hypertrophy with some dilatation of the heart.

Incisor Tooth in Orbit.

Dr. Ward Cousins recently showed to an English Medical Society an incisor tooth removed from the orbit of a child two years of age. It was very perfect in outline and structure. Mr. Tracey did not regard it as the product of a dentigerous cyst, but as a specimen of a displaced tooth during an early stage of development.

Hyperidrosis of the Feet.

In cases of undue sweating of the feet, accompanied by soreness and whitening of the skin of the sole, a cure may be readily affected by the application, once a day, of equal parts of citrine ointment and ung. aq. rosæ. The feet should be bathed frequently.

Correspondence.

Fracture by Muscular Force Alone.

Eds. Med. and Surg. Reporter:

I reduced a fracture yesterday of the right arm at the insertion of the deltoid in a boy 7 years old, produced by muscular force alone. He was pitching a base-ball. The rarity of such an accident in a perfectly healthy child of such tender years induces me to report this. The boy is very muscular and robust, never sick a day in his life. No constitutional vice in the family.

A. Ady, M. D.

Muscatine, Iowa, August 7th.

Asphyxia of New-Born Infants.

Eds. Med. and Surg. Reporter:

An article in your journal not long ago, in regard to the methods to be used in the asphyxia of the new-born infant, reminded me of a case of prolonged labor that I once had, where the child was apparently born dead, and where I used artificial respiration, hot and cold water, holding the child with the head down, etc., but ineffectually, and gave the child up, when the grandfather, who was present, said, "I can bring it to," and took the child and ran rapidly up and down a short flight of stairs three or four times. The second time going up the child had an inspiration, and in a few moments was all right. Since that time I have seen this tried quite a number of times, and always with good success; and if we stop to think of it, we will find that there is quite a physiological principle involved here.

Goffstown, N. H., Aug. 12, 1886.

How the Late Professor S. D. Gross Spelled the Word "Furnace."

Eds. Med. and Surg. Reporter:

After the Pittsburgh Cremation Society was established, being the first of the kind organized in the United States, the writer

received a letter from the eminent surgeon S. D. Gross, in which he inadvertently misspelled the word "furnace." The following is a copy of the letter:

"PHILA., *Oct. 7th*, 1883.

"DEAR DOCTOR: I am most decidedly in favor of cremation, and hope that my family will not neglect to place me in the fiery furness when I am gone. Fire is the only decent way of disposing of the dead. I am glad that you and your friends have taken this matter in hand, and trust that your influence may exert a powerful effect in overcoming the foolish prejudice which with many persons exists on the subject.

"I pray you to change the name of your association. Call it the 'Pittsburgh Cremation Society.'

"Wishing the enterprise all possible success, I am, dear doctor, with kind regards,

"Very truly your friend,

"S. D. GROSS."

The venerable professor in some way recalled his mistake soon after, for by the next mail came another letter, saying that he believed he had spelled the word furnace "furness," and that the only explanation he could make was that he must have been thinking of his old friend, the Rev. Dr. Furness, who opposed the idea of cremation.

The habits of accuracy of this great and gifted man were such that he would not allow so small an error as this to pass unacknowledged or uncorrected.

Kansas City, Mo.

NEWS AND MISCELLANY.

Toilers Among the Dead.

At a recent meeting of the Academy of Medicine, M. Brouardel made known some curious and interesting facts concerning the dead body of a girl, aged 22, which was discovered in a cellar under a heap of straw. The body had lain there about a year, and was in a perfect state of mummification. One of the limbs was shown at the meeting; it was thoroughly desiccated; the tissues were hardened, and gave a sound when struck. MM. Brouardel and Andouard attribute this mummification to the dryness of the soil on which the dead body had been placed; but the most important factors were five different species of acarina which deposited the *débris* of the envelopes of their eggs and carapace among the dust that covered the dried tissues of the body. M. Mégnin has proved that, by studying the generations of acarina which have been at work on a dead body, the date of death can be ascertained. This entomologist, by examining the *débris* of acarina in a child's corpse, ascertained that death occurred two years previously; and a judicial inquiry confirmed this statement. M. Brouardel described the order of succession of the different species of acarina which worked on the dead body of the young girl, also the work of destruction accomplished by each separate species: the gentles (larvæ of flies), *dermestes*, *sarcophagus*, *laticrus*, and *lucina cadaverina*. One species absorbs the fluids, another consumes the fatty acids. When a species has finished its work, it dies on the dead body, or is devoured by a succeeding species. Each generation in summer time lives from six weeks to two months. In a recent case of murder, M. Mégnin established with precision the exact date of the burial of the human remains discovered in the garden. Among the remains, a particular kind of ant was observed, which is never found in soil recently disturbed; also the *débris* of acarina, known as *Œsophagus echinococcus*, which also furnished a chronological indication; portions of a bulb of a lily furnished further proof. Two years must have elapsed in order that the bulb should undergo the alterations it presented. M. Brouardel dwelt on the value of these entomological data in reference to medical jurisprudence.

The Causes of Failure in Life.

The *Southern Trade Gazette* tells us that a literary client of the great Romeike has given that diligent newspaper clipper an order to collect information regarding causes of failure in life. Romeike, therefore, with his usual zeal, has issued one of the cruelest of circulars "to all curates of more than forty years of age, to all unknown barristers, and to certain members of Parliament and public men." We wonder what the unfortunates think when they find themselves thus stamped with the Romeike brand as patent failures, and a list of guesses at the names of the certain members of Parliament and public men who have received circulars would be instructive and entertaining. In journalism, if a man passes thirty-five without achieving success in his avocation, Romeike dubs him a failure, and sends him "a form of inquiry." This "form of inquiry" is too curious not to be printed in its entirety. It runs as follows:

To what causes do you attribute your fail-

ure in life? I, —— ———, of ———, profession ——, attribute my failure in life to the following causes:

1. Drink (say what drink).
2. Gambling (turf, cards, or what)?
3. Dishonesty.
4. Unfortunate acquaintances.
5. Marriage.
6. Single life.
7. Disinclination to work.
8. Lending or borrowing (say which).
9. Unpopular views (political); unpopular views (religious).
10. Tobacco (in what form).
11. General incapacity.
12. Other causes.

General remarks.

Medical Matters in the Argentine Republic.

The *New York Medical Journal* tells us that until within the last few years the study of medicine in the Argentine Republic was attended with much difficulty, and the facilities for instruction were very incomplete. For this reason many students went to Europe or to Brazil to pursue their studies. Now, however, there is a good school for medical instruction, and a hospital which furnishes ample clinical material. Formerly, anatomy, physiology, and pathology were taught only from books. Now there are a good amphitheatre for dissections, a laboratory for histological study, and one in which pharmacology is taught, and in a short time a physiological laboratory will be completed. The publication of medical books has been begun, and several medical journals are issued, among them notably the *Revista Argentina de Ciencias Médicas*, which is well edited and neatly printed. The project of establishing a Pasteur Institute in Buenos Ayres seems to be taking form. The National Congress has voted $5,000 toward its establishment, and the Provincial Congress has voted $3,000 for the same purpose. The executive commission reports that the president, Don Ignacio Pirovano, is receiving new accessions daily, and that the popular subscription gives promise of the most gratifying results.

The Negro from a Medical Standpoint.

Dr. P. Tipton, of Selma, Ala., in a carefully-written article published in the *Sanitarian*, gives some valuable facts regarding the negro race in the South. He first shows that their death-rate is over thirty per 1,000, more than double that of their white-skinned rivals. The death-rate among the blacks exceeds the birth-rate. The women usually have some uterine disease, which lessens their productiveness. Among the slaves, phthisis was unknown, but now the disease is four times more frequent among the blacks than the whites. Phthisis is now the greatest foe of the negro race. Malarial diseases are rare, and when they do occur, are of a very mild type. One-half the male population is syphilitic, but the disease is mild, and usually runs its course without treatment. Cancer of the womb is rare; lacerated cervix common. Deafness, insanity, diphtheria, and croup are also rare, while hysteria, rheumatism, and alcoholism are common. Unless the sanitary condition of the race is soon improved, it is threatened with extinction.

Sad Fate of a German Practitioner in South America.

The German residents in Bolivia wishing to obtain the services of a resident practitioner of their own nationality, recently agreed to guarantee some $3000 a year towards his support, and to allow him, besides attending the subscribers, to practice privately. A suitable gentleman was obtained, but unfortunately he shortly afterwards became insane. No satisfactory asylum being available in Bolivia, the German colonists tried to send him to Europe for treatment; but, though they offered a free return passage and a liberal recompense, they were unable to find any one who would take charge of the unfortunate doctor. However, from want of sufficient attendance he managed to escape, and nothing was heard of him till, three days later, a party of Indians brought him back with both his legs crushed. He was still alive, but was evidently fatally injured.

Culture of Vaccine in Mushroom Jelly.

Experiments have recently been made by the Finnish Medical Society in the cultivation of artificial lymph in sterilized mushroom jelly. The artificial lymph has also been dried and used for vaccination. A child was exhibited at one of the meetings who had been vaccinated by the artificial lymph in the arm. There were nine vesicles in three rows. They were all well developed, and did not present any dissimilarity, although two rows had been produced with lymph taken from different parts of the culture glass, and the third row with dried lymph from the same glass. Former experiments had not been so successful, owing to the resistance of the lymph to the effects of

drying. The condition of the lymph has now been brought to a more satisfactory point.

A Large Family.

One of the most prolific families of modern times lives in North Carolina. An exchange tells us that a gentleman traveling through the mountainous and thinly settled districts of that state was overtaken by a severe storm. As he was on horseback, and therefore quite unprotected, he beheld with delight a log cabin in the distance, and speedily betook himself thither. The old farmer greeted him with true Southern hospitality, and he soon found himself seated at the dinner-table beside "the old 'ooman," as his host designated his wife, while one by one a seemingly endless file of daughters entered the room. Turning to the farmer, he mildly observed, "You have a fine family of daughters, sir."

"Well," said the old man mournfully, "we've been kinder unfort'nate with our darters. The chimbly fell and killed all but nine on 'em."

The historian dares not guess how many of them there were at first.

An Excellent Example.

We are informed by the treasurer of the Ninth International Medical Congress that he has received, for the Congress, the sum of $500, donated by the Michigan State Medical Society at its recent annual meeting. The Executive Committee of the Congress must necessarily expend a large sum of money in printing and distributing circulars, and in perfecting all the arrangements preliminary to the actual assembling of the Congress. The liberal action of the Michigan State Society is timely and appropriate. It is very desirable that the good example presented should be speedily followed by the State Medical Societies of other States, and also by the leading societies in our most populous cities and counties.

The Birthplaces of Vegetables.

We learn from the *Popular Science News* that peas are of Egyptian origin. Celery originated in Germany. The chestnut came from Italy. The onion originated in Egypt. The nettle comes from Europe. Tobacco is a native of America. The citron is a native of Greece. The pine is a native of America. Oats originated in North Africa. Rye originally came from Siberia. The poppy originated in the East. The mulberry originated in Persia. Parsley was first known in Sardinia. Spinach was first cultivated in Arabia. The sunflower was brought from Peru. The walnut and peach came from Persia. The horse chestnut is a native of Thibet. The cucumber came from the East Indies. The radish originated in China and Japan.

Antisepsis in Military Surgery.

During the recent French invasion of Tonquin, the surgeons attempted to employ strict antisepsis in military surgery. The soldiers were furnished with antiseptic tampons for the immediate occlusion of wounds, a procedure which was found to be impracticable in the majority of cases. Carbolized sheets were used for covering the patients until they could be brought to the field hospital, where the wounds were washed and dressed antiseptically, and the patient left until operations, if necessary, could be performed. While the antiseptic methods succeeded in reducing the mortality among the wounded, the results obtained did not equal those of Reyher in the Russo-Turkish war.

Opposition to Pasteur.

On the 25th of July, at a meeting held at Paris and presided over by Dr. Chassaing, a municipal councillor, the methods of M. Pasteur were attacked by several medical men and veterinary surgeons. One speaker, M. Paul Bouiller, contended that microbes were not the agents but simply the products of decomposition. The very same microbes found by the professor in mad dogs could be equally obtained from the bodies of persons who had died of consumption. Dr. Bouiller concluded by challenging Prof. Pasteur to be bitten by a really mad dog. He (Dr. Bouiller) would submit to be bitten by the same animal. It would then be seen that the professor would go mad, and that he (Dr. Bouiller) would have cured himself by simple cauterization.

Imprisoned for Malpractice.

A Berlin physician has been condemned to two months' imprisonment for malpractice. A woman had an abortion followed by menorrhagia. The physician chloroformed her, with the assistance of a midwife, scraped the uterus with a sharp spoon, and injected liq. ferri sesquichloride. The patient died of peritonitis, and on autopsy several holes in the uterus were found, through which the injected fluid had passed into the abdominal cavity.

Nurses and the Hypodermic Syringe.

Under the heading of "High Nursing and Hypodermic Injections," the *Lancet* protests very properly against the practice of intrusting hypodermic medication to nurses, however well trained they may be. There is reason to fear that this ready method of drugging is practiced altogether too much, and its relegation to nurses even under instructions is undoubtedly calculated to encourage laymen in resorting to it themselves. The hypodermic syringe figures too often in the armamentarium of the morphia habitue, and it seems to be the duty of the profession to refrain from any measure, however indirect, that may tend still further to popularize it.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE WEEK ENDED AUGUST 14, 1886.

Carter, H. R., Passed Assistant Surgeon. Granted leave of absence for thirty days, August 12, 1886.

Glennan, A. H., Assistant Surgeon. Granted leave of absence for thirty days, August 9, 1886. To examination for promotion, August 12, 1886.

Pettus, W. J., Assistant Surgeon. When relieved at Savannah, Ga., to rejoin station, New Orleans, August 13, 1886.

The Importation of Rags.

Acting Secretary Fairchild has issued the following instructions to customs officers in regard to the importation of old rags: "All old rags imported into the United States in vessels which have passed local quarantine at the port of importation, will be admitted to entry in the same manner as other imported commodities, that is to say, without requiring special permits from the health officers as to their landing. The fact that the vessel has passed quarantine will be considered as sufficient evidence that her entire cargo is free from infection."

The Missouri State Board of Health and Medical Colleges.

At a meeting of the Missouri State Board of Health on July 12, the following resolution was passed:

Resolved, That in the future a percentage of graduates to matriculates of forty-five (45) or over, will be grounds for refusal of registration of diploma and issuing of certificate to graduates of a school otherwise in good standing; provided, however, that before such action is taken by this Board, the said school whose diploma is presented for registration shall be notified, and an opportunity be given the faculty thereof for satisfactory explanation to the State Board of Health.

In what Part of Boston is Massachusetts?

The *Indiana Medical Journal* says that Darwin states that the inhabitants of the South Sea Islands asked him in what part of London England is.

The proceedings of the new Association of American Medical Mugwumps, as quoted by the *Am. Med. Ass. Jour.*, states that eleven of the seventy-five are from Boston, and one from Massachusetts. We rise to inquire in what part of Boston is Massachusetts. The same for Pennsylvania (one delegate), and New York State (two delegates).

A Laconic Letter.

In *Harper's Magazine* for September we read that "in the days of '49," a member of a party of miners strayed away from his companions and was destroyed by wild beasts. The friend upon whom it devolved to "break the news gently" to the bereaved parents showed himself equal to the occasion by writing the following letter:

MISTER SMITH DEER SUR the Kiotes has ete yur sun's hed off Yurs

JOHN JONES.

International Congress of Climatology.

An International Congress of Climatology and Hydrology is arranged to commence on October 1, at Biarritz. A list of excursions into the Pyrenees and adjacent parts, which have been organized for the benefit of the members of the Congress, and which are spread out over the month of October, reaches upwards of thirty in number. Membership, the fee for which is fixed at 10s., confers the right to travel on the French railways at a reduction of fifty per cent., and entitles the member to join all or any of these excursions.

In Defence of Homœopathy.

A London paper states that it is proposed to establish an association for the purpose of dispelling the ignorance that prevails regarding the homœopathic system. The title of the new organization will be the Homœopathic League, and its objects are, in the words of the prospectus, first, "to give a

popular explanation of homœopathy, and to show that it is founded on reason, science, and experience; second, to defend homœopathy from the misrepresentations of its opponents, and to obtain fair treatment for it."

Medical Society of Virginia.

The session will convene in Fredericksburg, Va., on the night of October 26, 1886. The secretary's preliminary postal will be issued during this month, and prompt replies are requested. Applications for fellowship should be forwarded to the recording secretary (Dr. Landon B. Edwards, Richmond, Va.,), giving name and postoffice in full, name of college and date of graduation in medicine, reference to some Fellow who will recommend the applicant, and initiation fee of $2—the total annual expense.

A Sign of Death.

At a recent meeting of the Société Médicale d'Amiens, M. Lessenue mentioned the following as a simple and trustworthy sign of death. After pricking the skin with a needle the puncture remains open, just as when a piece of leather is pricked. On the living body, on the contrary, even if the blood does not come to the surface, as would happen if the person were hysterical, the pin-prick closes at once, and does not leave the slightest trace.

Items.

—Dr. T. H. Nott, of Goliad, was elected President of the Texas State Medical Assotion at its late session in Dallas.

—In the *Weekly Medical Review*, August 7, Dr. T. S. Washburn reports "a case of obstruction of bowels; twelve days stercoraceous vomiting; recovery; patient æt. 76."

—It is announced that the third volume of the Medical History of the War of the Rebellion is nearly completed, and will soon be issued from the press.

—Biniodide of mercury is insoluble in vaseline, but dissolves in 200 parts of lard or 50 parts of castor oil—a fact which should be remembered in prescribing it for inunction.

—The English hydrophobia commission is said to be retarded in its investigations by the difficulty of obtaining a rabid dog with which to test the efficacy of the protection afforded by inoculation.

— Deering J. Roberts has resigned the professorship of Theory and Practice of Medicine in the Medical Department of the University of Tennessee, and Dr. H. P. Waterfield has been elected to fill the vacancy.

—M. Bouchard has managed to induce cataract in rabbits by introducing naphthaline into the digestive canal. The quantity required for the purpose was a daily dose equal to a thousandth part of the animal's weight.

—The *St. Louis Med. and Surg. Journal* says that convulsions may frequently be cut short like magic by turning the patient on his left side. The nausea as an after effect of chloroform or ether narcosis may be generally controlled in the same manner.

—First Doctor—"I am sorry to see you in this condition, Doc. Who is prescribing for you?"

Second Doctor—"I am, myself."

First Doctor—"Great Scott! Don't do it! You are committing suicide."

—Dr. J. B. Hamilton, Surgeon-General M. H. S., and Secretary-General of the Medical Congress, 1887, has accepted the professorship of surgery in the Chicago Polyclinic. He will not resign his government position, but will spend his vacation in Chicago.

—An Arkansas farmer reports that last year, when coons made havoc in his cornfield, he went to the drug store to buy strychnine with which to kill them. By mistake the druggist gave him morphine, and next morning he found his field full of sleeping coons. He advises the use of morphine instead of strychnine.

—At a recent meeting of the Sei-I-Kwai (Japan) a vote of thanks was passed to Dr. H. C. Wood, of Philadelphia, for the donation of 105 volumes of valuable medical works to the Tōkyō Medical Library; a vote of thanks was also passed to Dr. Robert T. Wilson, of Baltimore, for the donation of nearly 200 volumes, including a complete set of Ziemssen's Cyclopædia, to the library.

—A Scandinavian customer was having a liniment prepared by a drug clerk, and calling for the ingredients by the five and ten cents worth. After it was supposed to be finished, corked, and delivered, he shook it up, looked at it, and said, "I will have five cents' worth of *nail olea* put in. Clerk was dubious, and the Norwegian explained, "I don't know how you call it in English; it is oil of big nail." "Oil of big nail, oh! Is it oil of spike?" and he answered, "Oh, yes, that's it, oil of spike."

Pallas Syringe. The most useful instrument for Vaginal Medication and Irrigation.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

GREEN SPRING SANITARIUM,
AND
WATER CURE.

For the treatment of all forms of Nervous Diseases, including the Alcohol and Opium habit; also diseases incident to Women, Rheumatism, Skin Diseases and Dyspepsia. Seventy miles west of Cleveland, in a natural grove of ten acres. Sixteen years successful operation. Means and appliances complete. Treatment by baths, electricity and ma sage, a specialty. One of the largest medicinal springs in America. Elegant apartments. Moderate terms. For particulars address **JOHN S. MARSHALL, M. D., Superintendent, Green Spring, Ohio.**

TAMAR INDIEN GRILLON.

A laxative, refreshing, and medicated Fruit Lozenge, very agreeable to take, and never causing irritation. Its physiological action assures the immediate relief and effectual cure of

CONSTIPATION,

HÆMORRHOIDS, BILE,
CEREBRAL CONGESTION, HEADACHE,
LOSS OF APPETITE,
INTESTINAL OBSTRUCTIONS, ETC.,

by augmenting the peristaltic movement of the intestine without producing undue secretion of the liquids. Unlike pills and the usual purgatives, it does not predispose to intestinal sluggishness, and the same dose always produces the same effect, that is to say, never needs increasing.

It is recommended by the most eminent physicians of Paris, notably Drs. BELIN and TARDIEU, who prescribe it constantly for the above complaints, and with most marked success.

Paris: E. GRILLON, 27 Rue Rambuteau.

MICRO-ORGANISMS IN GYNECOLOGICAL PRACTICE.*

BY S. PETERS, M. D.,

Of Cohoes, N. Y.

While it is our purpose to indulge in a few practical thoughts that are more particularly interesting to students of the diseases peculiar to females, it will not be out of place to allude briefly to bacteriology in general, especially as, at the present time, many have not given particular attention to its study, and even to those who have made special studies of micro-organic life, a frequent repetition of the lessons now considered proved cannot be time entirely lost. The importance of the whole range of topics is so great that it is not only our duty to study, but to make every technical term and every established point as familiar as our household words. The magnitude of the great lessons learned only through the microscope must impress all with the paramount importance of possessing and of becoming practically familiar with that wonderful instrument. The teeming myriads, invisible to our ordinary sight, have been for the past ages playing a general havoc with the higher orders of organic life, unseen and unknown; and while we are only just passing the threshold to the great arena before us, we have seen sights and gathered crumbs of the greatest value. We now study puerperal fevers and septicæmias from a far different standpoint, and already is human life far better conserved in these trying ordeals, as well as in others of the long list of zymoses.

The general term, bacteria, the plural of bacterium, includes all classes of micro-organisms. For convenience, they are divided into three classes, according to their different forms: the round or spherical, the long or rod-like, and the spiral or cork-screw shape. The round are called micrococci; the long, bacilli; the spiral, spirilla. These are subdivided, and include a large number of orders or varieties which it is not necessary to name here.

Each infectious or zymotic disease is supposed to be induced by a specific microbe that is capable of producing no other disease; that the specific microbe and the specific disease are inseparable and that the virulence of the disease is in exact ratio to the virulence or vitality of the microbe or its spore or germ.

All microbes must be and are capable of cultivation, so that generation after generation indefinitely can be produced. These cultivations must be, and are capable always of producing the same disease in which they were first found. The essentials of bacteria cultivations are a certain degree of warmth, moisture, oxygen, and a suitable soil or nutriment. The common potato answers admirably for many, perhaps most of such cultivations. This soil was first used by Koch, and has been of the greatest value in the study of bacteriology. Plates of pure gelatine are now much used, or strong solutions kept at a certain degree of warmth, according to the requirements of the particular bacterium.

The multiplication of micro-organisms is

*Read before the 2d District Branch of the New York State Medical Association, June 22, 1886.

either by division, commonly called fission, or the production of spores or germs, called sporification. When multiplied by fission, the cell constituting the microbe shows under the microscope at one point, generally near its centre, a stricture or narrowing, this becoming deeper and deeper until a complete separation takes place, thus forming two separate and perfect individuals; these, after a brief period, again divide, and so on to the rapid production of myriads in a few hours. When the increase is by sporification, two or more pearly or opalescent spots appear in the parent cell; these grow until finally the parent cell disappears. This last process is, I believe, always deferred till fission has been in operation for some time first.

The rapidity with which reproduction goes on is, according to the observations of Cohn, truly marvellous. He has carefully estimated that in three days' time, under favorable circumstances — plenty of food, oxygen, moisture, etc.—one bacterium can produce 15,000,000 of pounds, and in five days produce a bulk of 928,000,000 cubic miles.

This dangerous and fatal production would be speedily brought about were there not opposing actions or counter-actions. For instance, extremes of temperature is a common and easy method of destroying bacteria. The temperature of boiling water is fatal to nearly all of the pathogenic microbes. The temperature reached in fever is often sufficient for their destruction. The bacillus of anthrax cannot survive a temperature of 106° F. The relapsing fever spirilla cannot live when the thermometer reaches 104° F. On the other hand, the bacillus tuberculosis thrives at a temperature of 107° or 108° F. The tyrothrix bacillus, found often in certain kinds of cheese, will endure a temperature of 212° F. Spores endure a far greater range of temperature than their producing bacteria, some resisting a heat of 240° F., others a degree of cold far below zero. From some of the above-related facts it will be perceived that fever is not always undesirable.

Another efficient agency in the destruction of bacteria is the power or quality, whichever you may call it, of the lymph cells, wherever these are located: in the blood, in lymphatic glands, or on the surface of a suppurating sore. Whether it is a mutual affinity of these bodies for each other, or a battle for supremacy, the lymph cell imbibes the bacterium entire, where the latter is soon dissolved or lost. A single blood cell will thus receive several or many, but how long it can continue this action without injury to itself is not known.

Prof. Metschnikoff, I think, was the first to make these interesting and highly important observations. Other agencies are capable of destroying micro-organisms, such as the several chemical germicides. The comma bacillus, as observed by Koch, its discoverer, is rapidly destroyed by an acid medium, others succumb to alkalies, and all to a few substances, one of which, and at present, perhaps, the most popular, is mercuric bichloride.

The gynecologist has to deal principally with those particular organizations which produce sepsis or poisoning of the tissues. Now while the particular microbes of many diseases have been distinguished and accurately described, separated from others, cultivated, and found to reproduce in susceptible animals the same disease invariably, the investigations of experts in puerperal fever or puerperal septicæmia, as some prefer to call it, have not been so successful. It is true that single differentiated microbes have been isolated and even cultivated, and found to produce pathological states closely analogous to those found in the human body dead of puerperal fever; yet the evidence seems to point out a fact that more than one species of bacteria is capable of doing the same thing. Two of these have been named: one the *micrococcus septicus*, the other the *bacillus septicus*.

Dr. Noeggerath has very recently described in the *American Journal of Obstetrics* a coccus which has not been hitherto noted that I am aware of. In his own language, "its length, although somewhat varying in size according to the medium on which it is raised, is between a large coccus and a bacillus. It is a short rod, separated in the middle by a slight constriction just visible with a very high power, which gives it the appearance of two oblong cocci joined closely together. Sometimes two or three rods are joined in one. It is about one-quarter larger than the bacterium termo." This was found in a puerperal fever case of his which was very protracted and obstinate, and seemed to expend its poisonous action upon the tissue of the uterus without deposits in any remote organs. Besides this, Dr. Fraenkel has lately described a similar bacillus, though not identical.

It is probable that still other septic organisms have to do with the various operations upon and diseases of the female generative organs.

It is thus acknowledged that far too little

is yet known in regard to the number, natural history, etc., of this class of pathogenic bacteria, and that careful research is yet essential before we reach that perfection which has been attained in many other diseases. Much, however, very much, has been gained, as may well be seen by the statistics of several of our lying-in hospitals. At the Preston Retreat Hospital there were but two deaths in 756 cases of labor. (Goodell.) The Lying-in Institute in Dresden lost only 1.8 per cent. from metria, and only one case of septic disease in 570 births. (Winckel.) Previous to antiseptic precautions (in 1872), the death-rate was over 5 per cent. The mortality was reduced in Maternity Hospital in Copenhagen from 1 in 37 to 1 in 87. In the Emergency Hospital in New York the deaths are only two per cent. These figures are taken from the last edition of Dr. Lusk's work on obstetrics.

We may now ask the question, How do pathogenic bacteria produce disease? Some affirm that by the rapid increase in numbers simply the normal operations of the economy are so interfered with that disease is the result. In support of this, it is well known that blood-vessels are sometimes actually choked by the myriads of these organizations, and further, that the vast amount of oxygen required for their development must interfere with the physiological requirements of the body.

Others believe that the blood-globules, particularly the white cells, are greatly injured or entirely destroyed by the entrance into them, in too large numbers, of these organizations, as has been shown; this power of the white cells, ordinarily so favorable, being now overwhelmed and themselves destroyed. No doubt in some cases this is a powerful factor.

Still other theorizers, and particularly those who are opposed to this germ theory of disease, maintain that septic products are formed in the body by ordinary chemical or vital action—these poisonous ptomaines, as they are called, sometimes forming in quantity sufficient to react upon the body and produce disease.

It is improper here to follow the successive steps taken in the evolution of this theory, largely brought out by the researches of M. Gauthier. It is at the present time well known that, as shown by this observer, such toxic products are formed and found in the animal body, and that while some of them are formed by the oxidation of tissues within the body, other like products, even more toxic, are the result of the agency of bacteria. Koch is of the opinion that the comma bacillus secretes or excretes a ptomaine whose reaction upon the tissues may be the efficient, or one of the efficient causes of Cholera Asiatica.

In carefully studying these various theories in answer to the question, How do bacteria produce disease? the opinion seems justifiable that all these agencies are combined in inducing the general result, namely, what we call disease; that the bulk of numbers, the urgent demand for, and great consumption of oxygen not supplied from the external air, the injury or destruction of the blood-globules, and the poisonous action of the bacteria secretions called ptomaines, all together act to produce the pathological result. We may take it for granted, then, at least for the present, that disease results from—

1. Great numbers of bacteria.
2. Great waste of oxygen.
3. Injury of the blood-cells.
4. The toxic action of one or more of the ptomaines.

We now come to the more practical part of our subject, namely, the management of gynecological cases of disease induced by micro-organisms. The indications seem clear —1, to prevent the entrance of pathogenic microbes into the body; 2, to aid as far as possible all the efforts of such infected body to rid itself of them, and of their effects. Nearly the whole subject of treatment is therefore included in what is known as *antisepsis.*

This mode of treating infectious diseases is yet in its infancy, we might almost say in embryo; yet who will deny that it has earned for itself, in its brilliant results, the thoughtful attention, if not the hearty endorsement, of the mass of the medical profession? We cannot ignore the fundamental principles of this comparatively modern theory, because actual demonstrations are by no means wanting. Willingly or unwillingly, we are forced to heed its foundation precepts in our daily rounds.

It would be impossible here to enter into all the details of antiseptic medicine. The search for antiseptic agents and procedures has been well repaid, and yet greater discoveries are undoubtedly to be made in the near future. I prefer to spend what little time is remaining to me in attending to only a few points that are perhaps the more prominent.

A few weeks ago Dr. Howard A. Kelly read a paper before the Obstetrical Society of Philadelphia, an abstract of which is published in the *New York Medical Journal.* The abstract is headed "Asepsis, not Anti-

sepsis," and it so well represents my own views that the reading of it would well repay for the time spent. Dr. Kelly uses excellent reasoning in his preference of asepsis —that is, cleanliness and general hygienic precautions—in preference to any and all kinds of antiseptic treatment, strictly so denominated. He refers principally to the objectionable use of carbolic acid and mercuric solutions, and refers more particularly to their use in abdominal surgery. I am quite strongly impressed, after some little experience, that the same is true with regard to their use in the puerperal septicæmias. The solutions of these germicides, of such strength as to be in any degree efficient, are too strong to be applied to any abraded part of the body, particularly to the vagina and uterus, where, as all must admit, much harm has already been done. In the language of Dr. Kelly: "The patient is very often killed along with the germs," and he then quotes the words of Dr. Goodell: "The first four cases done in the theatre at the beginning of last session had hemorrhage from the kidneys, and two of them died. It was purely carbolic acid poisoning; of that I have no doubt whatever." It is well known that Lawson Tait uses nothing but water and soap. C. Fürst strongly cautions against the use of these antiseptics, *Medical News*, December, 1885. Salivation has been induced by a 1 to 2,000 solution of mercuric bichloride used as a vaginal injection. Goodell is opposed to the use of these antiseptics, emphatically to their application to the cavity of the uterus. And so we might go on with references against the use of these two agents and their congeners, to almost any extent. Yet, strange to say, they are still fashionable in many quarters. For cleansing the hands, instruments, tents, sutures, and other appliances, they are indispensable; but for applications with a view to the destruction of microbes, they should be well-nigh discarded.

Water in my hands serves as the safest and most efficient antiseptic. Water is the great cleanser, and may be used freely and everywhere. As the great Lawson Tait remarks, "tap-water is all sufficient." Lusk says, "distilled water renders the action of bacteria extremely feeble." Keith uses antiseptics sparingly. Hiram Corson, of Pennsylvania, delights in deriding the fashion of flooding the uterus with anything but water, and seldom with that.

Fortunately for our race and for the advancement of true science, hygiene is asserting her lofty position in the conservation of human life. The power acknowledged for antiseptics may wane, hygienics never. Gynecologists, as well as others, have learned this well. Cleanliness cures septic diseases by forbidding even the presence of any and all noxious agents. Keep ourselves and our patient clean, and fear not—waiting, however, for the ideal germicide and antiseptic that may be discovered to serve as the handmaid of cleanliness.

THE DOCTOR AS A SANITARIAN.

BY THOS. W. HARVEY, M. D.,

Of Orange, N. J.

I do not mean the doctor as a sanitary engineer, or the author of a sanitary tract, or as a member of a board of health, but in his daily avocation of adviser on his daily round of visits.

It is in the details of every-day life, in the management of the household, in the practical application of sanitary principles to housebuilding and housekeeping, in the education of his patients in proper ways of living, in the application of those great principles which, a rare compound of scientific thought and good common sense, constitute that new department of knowledge, sanitary science.

The interest in this science is widespread, its literature is already voluminous, its professors are recognized authorities working for the good of the community; but its quackeries are also becoming prominent, and in few other departments of learning does so much "half-truth" pass for law and gospel. The proprietor has but to cry up some weak combination of salt and carbolic acid as a great parasiticide, putting in his advertisement a lot of gush about sanitary laws, bacteria, Pasteur, etc., etc., when its sale is assured. The people are receptive of all such stuff, their minds having been carefully prepared for its reception by the close study of the scientific column of the religious weekly. This imperfect knowledge of sanitary facts is not confined to the laity; it is the rule in the professson, and should be corrected. No person in the community may have more influence for the spread and acceptance of correct knowledge on these matters than the physician. There is no one whose opinion is asked oftener. He is the one of whom first the head of the family asks the question, "Is there anything the matter with my drainage?" How ready every doctor is to answer the question! It does not look well not to know, not to be able to say just where the trouble lies. It

redounds so to his credit in the community to have it said that "The doctor looked over my pipes and pointed out the difficulty at once. *I had no traps.*"

It is my experience that not one physician in ten is qualified to make such an examination. And I might go further and say that very few *know* that such an examination is impossible in nine-tenths of the houses that have been built more than five years.

This state of affairs is very much what it is in medicine proper. The opinions prevalent among the laity are what passed for facts and true theories among the last generation of medical men. We are to-day combating among the people the errors that our fathers in medicine combated in the profession. So in sanitary science what passed muster as good practice fifteen years ago with the professed sanitarians, is still considered the highest kind of sanitation among the people at large and the mass of medical men. We are not keeping abreast of the times. For instance, some ten or fifteen years ago the trap was considered the magnum opus of sanitary skill. Stick a trap on a pipe, and the terrible gases that cause disease, the sewer gas, was imprisoned and done for: it was a stopper that was hermetical. But it took but little time and common sense, and the application of known physical laws, to demonstrate that the trap *per se* was useless. In some places, as between the foundation of the house and the street sewer, it was not only useless, but actually harmful, preventing that free circulation of air through the pipe system, that is the most active and only successful disinfectant agency that can be applied.

Again, this same "sewer gas" has come to be considered a misnomer, or at least a misapplied term. Sewer gas there undoubtedly is; at least in every receptacle containing decomposing organic matter there are present the gases resulting from such decomposition; but those gases that make bad smells in the house do not come from the street sewer. Said a well known sanitary authority, in a recent lecture: "I know of no instance where a bad smell is found emanating from plumbing fixtures that have *not been used*, although connected with the public sewers for some time."

The proper term to be used is "*fixture*" *gas*, and I think the importance of a proper name is evident. The name suggests the treatment and is the basis of the modern arrangement of pipe systems in houses. The aim is not to keep sewer gas or air out of the pipes, but to so arrange the system that what gets in may easily get out, and also that plenty of good fresh air may continually flush them and purify the foul gases that are formed in them.

I mention these instances as indicative of the changes that have taken place and are taking place in the minds of those who are working most actively in this great art of preventive medicine, and because I find such crude ideas prevalent in the profession.

Most medical men are still in the trap and sewer gas period of their sanitary development.

A man imagines that by walking into a bath room, smelling at a wash basin, and calling a closet by its particular name, that he is thereby constituted a sanitary authority, and that he has made an examination from which he may give an opinion that may involve the expenditure of much money to rectify.

I do not want to urge that every doctor should be a sanitary engineer or a practical plumber, but that he should either cultivate a more practical acquaintance with sanitary science, or should have the grace to say that he does not know enough of it to express an opinion. Perhaps at the present time this is all that should be asked. But the physician should know as thoroughly the principles of practical sanitation as he does his anatomy or physiology, particularly the general practitioner, who every day is becoming more and more the *counsellor* in health matters. The specialist is gradually getting away his "practice," but his "advice" is sought more than ever, if it is only to ask to what specialist the patient shall carry his ills; and indeed it is getting to be a serious thing, and a position requiring much judicial acumen, to decide whether the invalid is to be sent to the neurologist, gynecologist, or oculist.

It is evident to every one that more advice as to the way to avoid future sickness is expected from the general practitioner than formerly; and that he may fulfil this duty properly, a much more profound and exact knowledge of sanitary principles is necessary. I think it is the duty of the profession to urge the establishment of chairs of practical hygiene in our medical colleges.

It is also well to remember that the duty of the physician covers the recognition of the causes of disease and wrong conditions generally, but does not necessarily include the details or method of correction.

Another field where the physician is specially needed at present is in correcting the great amount of misinformation that prevails popularly among our people, and to stay the

great streams of error that threaten to drown out the little knowledge that we now have. These are the times when the great "anti" societies flourish, and this sanitary movement has been prolific in the production of "cranks," full of half-digested facts and crude theories which they disseminate among the people, to many of whom such praters appear as disciples of light and the only possessors of true knowledge.

It is time then that the well-informed physician should recognize that this field is one in which he should be the best informed man in the community. He should be the source to whom all should look for their information regarding health, both for restoration and for preservation.

Every physician represents a circle to which he is already an authority in most matters in curative medicine; perhaps by a certain number he is counted second to the medical almanac, but there are a few people among whom his opinion is final. If he decrees death, they die; if he formulates a rule of life for the preservation of health, they will follow it implicitly and will preach it to others.

How necessary then that he should know thoroughly the "reasons why" of our sanitary rules. I know of no department in medicine that requires more of that hard common sense that is the characteristic of the successful general practitioner than the correction of sanitary evils. On the other hand, there seems also necessary the cultivation of a faculty for seeing what lies before the eyes, and of recognizing bad conditions when present.

Every doctor, therefore, who acts as a family physician, should know first what to look for and then where to look for it. It is not necessary that he should ride on the crest of the bacterial wave, or that he should feel perfectly satisfied that he knows exactly the cause of scarlet fever or diphtheria—better not: the fewer preconceived opinions he has, the less his mind is occupied by library-made theories, the more likely he is to see what actually exists, rather than what he expects to find.

There are a few cardinal principles that should guide his search.

Whatever changes the air that we breathe from its natural condition is an impurity.

The same proposition holds good as to food and drink.

The most useful disinfectants are the sunlight, the oxygen of the air, and pure water. Dilution is nature's method for purifying the air, aeration for purifying the water.

Whatever is a source of impurity to the air we breathe renders us liable to disease by depressing the vital forces and weakening the normal resisting power of the individual tissue cells. The same is true of impurities in water or food.

Any system of sewage collection, carriage, storage, or disposal that does not provide for thorough ventilation and flushing both with air and water, and give plentiful opportunity for cleansing, is faulty. The mechanism is unimportant, so the object sought is well recognized, which is not the getting rid of the waste of animal life in the speediest manner possible, but the return to its original elements of the products of the decomposition of this animal waste in such a rapid and complete way that it may not add impurities to our air and water, or food.

It is not within the compass of this paper to point out the application of this rule to the plumbing of a house, for instance. But if such a system is not made to comply with the requirements of this rule to the letter, it will be a source of ill-health to those who are served by it.

Every physician who will approach these problems with his mind unbiased by previous speculations as to the causes of diseases or as to particular systems of drainage, or in the larger field of the management of epidemics, and will apply to them the same methods of reasoning that he uses in the study of diseases when established and their cure, will find that they are usually easy of solution and productive of much mental gratification to himself. Further, by so much as he becomes familiar with the recognition and treatment of insanitary conditions, by just so much he becomes a more useful member of society, and a more valuable adviser to his patients.

CONTAGIOUSNESS OF TYPHOID FEVER.

BY JAMES E. FREE, M. D.,

Of Emporium, Pa.

In the *Medical News* for July 24, 1886, is a contribution to the literature of typhoid fever which discusses hepatic abscess as a complication. So much has been written upon this subject, namely, typhoid fever, that it would seem as if our knowledge ought to be perfect.

But this paper is an illustration of the fact that careful observers still find things rare enough to be interesting. Hepatic ab-

scess may have occurred a number of times since the days of Hippocrates, but it is one of the few phenomena which has escaped getting into print, and, of course, when some of us stumble upon a case, we suppose that ours is a freak of pathology. It is not safe to claim the credit of a discovery in any science, for no sooner is our boast heralded in the press than a cloud of witnesses arise to prove that we have been anticipated by some poverty-stricken genius who died of a broken heart because his ideas were rejected by an unfriendly world.

Knowing well the ground I stand on, and desiring to dispute no man's title, I would like to put on record some experience of my own within the past year. Every effect must have a cause; but it is not always easy to place our hands on it. This fact accounts for the superabundance of theory produced by mankind. Whatever may be responsible for typhoid fever is widely disseminated, for the circle of its influence extends around the earth.

Dr. Gerhard's remarks on the epidemic at Rosemont, Pa., are doubtless correct, but ever since leaving college I have sought for "confirmation strong as proofs from holy writ" of the teaching of my *alma mater*, and I am bound to say that hard as it is to give up a doctrine which is rooted and grounded in faith, my search has met with indifferent success.

The case which I wish to speak of at the present time occurred in a boy fifteen years old. For two weeks previous to my first visit he had been complaining of being tired; but he has the reputation of having a chronically tired disposition, and his parents suspected him of malingering, and did not attempt to do anything for him until the middle of October, 1885. I saw him October 17, he was then complaining of violent pain in his stomach; there was no desire to vomit, his skin was dry and hot; temperature on the evening of first visit 103½°, respiration 24; tongue was covered with an abundant yellowish coating, the bowels were constipated. No positive information could be obtained as to when there had been a stool. The boy declared he had not been out of the house for nine days, but of course in his condition the statement should be taken with a grain of allowance. The pulse was 100, and on account of the arrest of the biliary function the face, which was flushed and dark, looked like a turnip after sticking out of the ground too far all summer, and being exposed to the scorching rays of the sun. I had had a similar case some time before in the same neighborhood, which was ushered in with agonizing intermittent pains over the region of the liver, and had incautiously made a diagnosis of gall-stone. This time I remembered that prudence is the physician's cardinal virtue, and husbanded my diagnosis, as it were, and resorted to stimulation—a practice first learned from my friend, W. H. De Long, M. D., who says that it is policy to maintain the strength of a typhoid patient by the constant use of alcohol when the temperature reaches 102°.

By the way, a remark which is not germane to the subject suggests itself. Examining surgeons for the pension department will call to mind the extravagant claims sometimes made with regard to the sequelæ of typhoid fever. Civil practice proves that the subjects who escape the death penalty usually recover their health and strength rapidly and permanently, and it is remarkable if there is any wide variance from this rule in the same disease contracted while on the march or in camp. A man, for instance, had an attack of enteric fever in 1863, and now comes before the surgeon for examination. Supposing he recognizes the symptoms of incipient Bright's disease, namely, increased arterial tension, increased apex impulse and cardiac dullness, and ventricular hypertrophy, is he justified in saying that the ex-soldier is entitled to a pension on account of disability received during service? These lesions he knows to be compensatory, and therefore hardly likely to have existed for a score of years. Such are the difficult problems which may have something to do with the veto of pension bills.

But, to return to my patient. There were nine in this family, and as I studied their surroundings, which were very far from the standard of hygiene and sanitation, I became convinced that at last Providence had put me on the track of contagious typhoid fever. So a book to note the particulars of each case as it developed was prepared.

Different localities are not alike susceptible to typhoid fever, unless in the time of an epidemic—then indeed no barrier is strong enough to protect us. My patient lived in what is known as Rich Valley, northwest of Emporium. It is nine miles long, and perhaps on an average a quarter of a mile wide; its outlet is just at the upper end of the town. On the south, west, and north it is bounded by mountains. One peculiarity of the inhabitants is the fact that, like our remote ancestors, they have descended from a common stock. Several generations ago the valley was settled by two or three families,

and their descendants have married and cohabited until the genealogy of the valley is involved in inextricable confusion. As far as can be discovered, there is nothing peculiar in the topography of the valley, excepting that it meets the mountains at its upper end. It is as well watered by creeks and rivulets as neighboring portions of this district, and the soil, judging from the abundant crops, is equally fertile; but here typhoid fever is rampant. No other disease occurs with such frequency, with the exception probably of *confinements.* (?)

Another remarkable fact to my mind is the exemption which Emporium enjoys with regard to enteric fever. Considering that the creeks which drain Rich Valley feed the stream along whose banks our town is built, what is the explanation of this exemption? An immense tannery is located at the outlet of the valley, and its refuse is emptied directly into the creek. Is it possible that any disinfectant properties are inherent in the waste of tanneries? The miserable stench which ascends towards the heavens may, in that event, be a physiological blessing, but there are sojourners here who think it is a deeply-disguised blessing.

There was nothing peculiar about this case of typhoid fever—it progressed as ordinary cases are prone to do—but what seemed strange to me was the immunity which the rest of the family enjoyed; they lived in a state of semi-poverity, and the younger members of the family spent a large portion of their time tumbling over their brother's bed; but not one of them, however, has had the prodromal symptoms of the disease.

Prof. John S. Lynch, of the College of Physicians and Surgeons, Baltimore, used to say that typhoid fever sometimes occurred in such a mild form that the patients were hardly conscious of anything being the matter with them. It might have been thus in this instance. Another of the professor's pet ideas was the power of heroic doses of quinine to abort typhoid fever. This I have tried in several cases of suspected typhoid, but when no further symptoms of the dreaded malady developed, my conscience condemned the diagnosis, and made me doubt whether I had not been like Don Quixote, fighting an imaginary foe.

At the end of the fifth week the boy, who up to this time had been progressing nicely, began to complain of pain in his side; to use his own words, he felt as if he "had a bile in his belly." The liver was considerably enlarged and interfered with the action of the diaphragm, and also prevented expansion of the lung. A distressing cough ensued, and the temperature of the body fluctuated between wide limits, sometimes being subnormal, as low as 94° once. At the time I attributed the low index to some fault of my thermometer, but now know that it is characteristic: there were now profuse sweats, occasional chills and hot flashes, and emaciation.

It was about two weeks from the inception of the hepatic trouble that heroic measures seemed to be demanded, and I resolved to resort to something effectual in the morning.

During the night of November 30, 1885, the Warner House, one of the finest hotels in this section of the State, was burned to the ground, and a number of the guests seriously injured by jumping from the roof and windows. Consequently, the physicians of this place had their hands full for a number of hours, attending to the wants of the suffering. The next day I was unable to attend to practice, and in a few days developed an attack of genuine typhoid fever. More than a month afterwards, when I was again able to go about, I found that the boy had passed about a quart of "yellow matter" per rectum, and afterwards recovered, as if by magic.

Now, what I am studying over at the present time is this—why a man who, so to speak, had obeyed the commandments of prophylaxis from his youth up, should be stricken down with a disease which a family who lived within constant reach of its deadly germs refused to contract?

Medical Societies.

THE PHILADELPHIA NEUROLOGICAL SOCIETY.

Stated meeting, March 22, 1886.

The President, S. Weir Mitchell, M. D., in the chair.

Dr. H. C. Wood read a paper on

Landry's Paralysis.

In the course of the paper the symptomatology and diagnosis of neuritis and poliomyelitis were to some extent considered.

Dr. G. Betton Massey said that in regard to pain on pressure in poliomyelitis, that it is of interest to recall the fact that in this affection the skin is unusually sensitive. In children, for a year after the attack, there is hyperæsthesia to tactile impressions and especially to the battery. Hyperalgesia

would probably better describe the condition. These cases have presented marked reactions of degeneration, and it has seemed to him that the greater the reactions of degeneration the greater the sensitiveness to the galvanic current in children. An autopsy is by no means necessary to make out the diagnosis, for the clinical histories of these cases are almost identical. It should be as easy to diagnose acute poliomyelitis in a child as to diagnose small-pox. He thought it might be possible, in the cases referred to, to remove a portion of the nerve for examination during life.

Dr. Wharton Sinkler, in reply to Dr. Wood's statement that the diagnosis cannot be regarded as proved unless there has been an autopsy, said that we cannot make autopsies in all cases, and we must therefore infer that our diagnosis is correct when the symptoms are identical with those of other cases in which autopsies have been made. Competent observers in this country and abroad have made post-mortem examinations in cases of infantile paralysis, and have found distinct lesions in the anterior horns of the cord. Hence we may assume that there is such a disease as poliomyelitis anterior. He had seen children, as described by Dr. Massey, in whom there was hyperæsthesia to electricity, especially to the galvanic current.

At least twelve or fifteen years ago Barnwell advanced the view that infantile paralysis was a disease of the peripheral nerves; the later observers, supported by autopsies, seemed to have disproved his theory. Kennedy has described a variety of infantile paralysis under the name of temporary paralysis. We believe that this disease is distinct from "myelitis of the anterior horns," and it may be the result of a diffused neuritis, as suggested by Dr. Wood. He had no doubt that some of the cases of the so-called spinal paralysis of adults, those of short duration, may be of a similar nature.

Dr. Francis Dercum had lately seen a case in private practice which was of interest in this connection. A man who had been exposed to damp and cold had a chill followed by fever. He was called to see him, and found him suffering with intense pain affecting both brachial plexuses, followed by rapidly developing paresis of both arms. This was evidently a case of peripheral neuritis. The electrical reactions were examined by Dr. Lloyd, who can better give the results of this examination.

In such a case, if the patient does not die early, we may expect the cord to become involved, and then, in the absence of a knowledge of the previous history, it would be impossible for any one to say which was the primary lesion.

He thought it possible that we may have a disease in which both the centres and the nerve trunks are affected simultaneously. Diphtheritic paralysis is probably a case in point.

Dr. James Hendrie Lloyd thought that the case referred to by Dr. Dercum was of interest, especially with reference to one or two points which had been brought forward in regard to the reactions of degenerations. This man was completely paralyzed in both deltoid muscles, and in the right infraspinatus and the right teres major and minor muscles. The left infraspinatus and teres muscles were perfectly normal. If this was a case of peripheral neuritis, we have facts contradicting some observations made to-night. In this case, typical reactions of degeneration were present. The changes were both serial and modal, and the faradic irritability was almost extinct. There were no fibrillary contractions in this case. In regard to this subject of reactions in wasting muscles, it seems to him that where there have been marked fibrillary contractions, the reactions of degeneration are not as distinct as we should expect to find them, and this is probably due to the fact that such cases are caused by a slowly advancing anterior poliomyelitis, in which the trophic centres are very gradually destroyed; whereas, in peripheral neuritis the lesion would be more quickly established, and the characteristic electrical changes would be earlier observed.

Dr. Charles K. Mills thought that while multiple neuritis may occur more frequently than we have been led to think, still, we have as yet few positive diagnostic points. Pain on pressure over a nerve trunk is perhaps one of the best signs of neuritis of all forms, but this is also sometimes found in subacute myelitis of the anterior cells, and in neuralgias there is hyperæsthesia at limited points. In genuine posterior sclerosis at times limited areas of pain on pressure are present. In regard to Landry's paralysis, it seems that subacute myelitis of the anterior horns would simulate it more closely than anything else.

Some years ago, Leyden advanced the view that locomotor ataxia was due to neuritis, and since then this view has been advocated by different authorities. We find tenderness over the nerves in various spinal and cerebral affections. In some cases of brain tumor, hyperæsthesia is a marked feature. The same is sometimes seen in spinal tumors.

It might be said that in these cases there was also neuritis, but in some cases of brain tumor this is impossible. The tumor may be so high as to be remote from the nuclei of origin of the nerves. Leaving post-mortems aside, the uniform bilateral character of many of the cases classed as subacute anterior poliomyelitis is, so far as it goes, in favor of a central origin of the disease.

The suggestion of Dr. Dercum that the disease may simultaneously affect the nerve trunks and the centres seems more philosophical than to attribute all these cases to multiple neuritis. In arsenical paralysis, he believed that the nervous protoplasm was everywhere affected.

The Use of Nitrite of Amyl in the Severe Paroxysms of Whooping-cough.

By Dr. Morris Lewis.

E. B., female, æt. 13 weeks; breast-fed; a well-formed, healthy baby; rather small, and weighing about seven and one-half pounds.

At the age of seven weeks, having just recovered from the effects of a perfectly normal vaccination, she contracted whooping-cough from her brother, whose case had been one of the lightest character, rendering the diagnosis impossible for over two weeks. The infant's cough for the first week was but slight; but during the second week it began to show the characteristic symptoms.

The child was placed upon a mixture of belladonna and alum every three hours, and progressed favorably until the night of February 12, which was towards the end of the second week of the disease; it was then seized with a violent paroxysm of coughing, became purple in the face, and finally, according to the mother's statement, ceased to breathe. I was immediately sent for; but before I could answer the summons, the mother had thrust the child out of the window into the cool, damp air of a foggy night. This procedure was immediately followed by an inspiratory effort, and the child breathed again. When I arrived, the child was in an exhausted state, and was breathing regularly. After this, until the 22d of the month, but one other slight attack of this nature occurred. By this time the child was coughing in a perfectly typical manner. The medicine was continued, but in slightly larger doses, the child taking about the one-twelfth grain of extract of belladonna in the twenty-four hours.

On the night of the 22d there were three severe paroxysms, during all of which I was present.

The child would awaken with a series of violent expiratory coughs, with scarcely an inspiratory effort between them. Finally, an expiratory spasm would occur, lasting fully fifteen seconds, during which the child would struggle and become perfectly livid. This would be succeeded by complete collapse, with entire suspension of respiration, due probably to exhaustion of the respiratory centre.

During the last two of these attacks I administered ether by inhalation, and believe that thereby the spasmodic stage was somewhat shortened; but the subsequent collapse was so severe that I was obliged to resort to artificial respiration, and once had to continue it for ten minutes, as during that time there were but one or two feeble attempts at inspiration. The evening before I had placed the child on the $\frac{1}{600}$ of a grain of sulphate of atropine every three hours.

Dr. William Pepper then saw the case with me in consultation, and suggested combining a small amount of nitrite of amyl with the ether to prevent if possible the stage of exhaustion. This combination seemed to have a good effect; but, as the amount of ether required seemed to render the child drowsy and disinclined to nurse, I gradually diminished the proportion of ether until the mixture contained one-fourth part of nitrite of amyl. This mixture was kept in a small vial, and with each cough the end of the finger was wetted with the mixture and held close to the child's nose and mouth, so as to catch the first inspiratory effort. Thus administered, the child practically got nothing but nitrite of amyl. After the commencement of this treatment the child never had another attack of exhaustion, and the severity of the paroxysms seemed to be lessened, although the child coughed just as frequently, the number averaging fifty in the twenty-four hours, the amyl being given each time.

No untoward effects were at any time noticed, even when once I held the bottle, containing at least 10 drops of amyl, to the child's nose.

It was difficult to judge of the amount of flushing produced by the drug on account of the flushing caused by the cough.

I am confident of the beneficial effect of the nitrite of amyl in this one case, and although one swallow does not make a summer, I think the drug will be found of use in analogous cases.

Dr. John M. Taylor, who assisted me in watching the case, is also positive of the good effect produced.

In the short time that I have had to look up the literature of the subject, I cannot find that nitrite of amyl has been used in

whooping-cough, nor has anybody that I have spoken to on the subject known of its use.

By diluting the nitrite with ether or alcohol, it can be administered in any dose required, and could more easily be placed in pearls than the pure nitrite.

By placing it in a bottle with a small top, that can be covered easily by the finger, it can be almost immediately administered by simply wetting the tip of the finger by inverting the bottle.

The child is now doing well, and has had no complication other than a slight umbilical hernia.

Stated meeting, April 26, 1886.

The President, S. Weir Mitchell, M. D., in the chair.

Dr. H. F. Formad, by invitation, read a paper and presented specimens illustrating

Different Forms of Cerebral Hemorrhage.

Dr. Dercum said that Dr. Formad states that in no case can the blood find its way from the pia mater into the ventricles. That is true of the general surface of the brain, but not of the base. Profuse hemorrhage at the base may find its way into the lateral and third ventricles through the transverse fissure of the brain: of this he had seen an instance.

Dr. Charles K. Mills thought that perhaps the statement in regard to the first class of cases may be misleading, if he says absolutely that small hemorrhages in the fourth ventricle and in the lateral ventricle occur only from traumatism. These are of frequent occurrence, particularly in the floor of the fourth ventricle in many diseases. They probably take place at the time of death. He has seen them in cases dying in the epileptic status. They have been found in cases supposed to be hydrophobic.

The occurrence of the hemorrhage in the second class of cases opposite the point of application of the force is interesting, and he thinks is best explained by Duret in his papers on traumatism. He attributes it to displacement of the cerebro-spinal fluid with the formation of numerous vacuoles and the rupture of the blood-vessels from within outward, the largest vacuoles usually occurring opposite the seat of injury. In those cases in which the hemorrhage is in the lenticular body and works its way into the lateral ventricle, numerous ecchymoses occur in various parts of the membranes and of the brain. These occur for the same reason as when the skull is struck from the outside.

He believed that in children hemorrhages occur beneath the pia mater without any special recognizable cause. He has seen one case in which meningeal hemorrhage occurred in a new-born child, probably as result of traumatism from the use of forceps. Where children die soon after delivery, he believes that death is sometimes due to this cause.

Dr. Charles K. Mills reported a case of

Unilateral Sweating.

The patient was an unmarried woman thirty-four years old, sent to him by Dr. Deakyne. Eighteen or nineteen years ago she began to have spasmodic attacks which seemed, from description, to be epileptic. About fourteen years ago she had a stroke of left-sided paresis. About the same time she began to perspire excessively on the side of the paresis. This unilateral sweating has continued up to the present time and is more marked than before. The secretion on the right side is normal. There is also increased lachrymation on the left side. The saliva seems to be about in equal amount on both sides. Before the occurrence of the spasms she complained of a peculiar taste, probably metallic. She occasionally has slight attacks of dizziness, is somewhat absent-minded, and at one time had severe pain in the head. Four years ago the spasms ceased. The left side of the mouth is visibly drawn a little upward. There is slight paresis of the muscles supplied by the facial nerve. She cannot draw up the left side of the mouth volitionally as well as the right. The slight loss of power in the limbs of the left side is more particularly in the arm.

She has had no trouble with the bladder or bowels. At times the left side of the face reddens very much and remains so for some time. She has some pain on the left side. She has been chiefly treated for uterine trouble. She does not present any signs of the hysterical temperament. Against hysteria are the facts that, in the first place, she has paralysis of the muscles supplied by the facial nerve; second, she has contracture on the left side, which is sometimes present in old cases of facial paralysis; and, third, the persistence of the condition for fourteen years.

Dr. Edward T. Reichert thought that it is not only probable that sweat centres exist in the spinal cord, but also that there is a dominant centre in the medulla oblongata. The latter is no doubt bilateral, and while it generally acts as an individual centre, affecting in like degree sweating on both sides, the centre on one side only may be in a condition of over-excitement, as is probably the condition in the present case, thus causing unilateral sweating. The lesion must, he thinks, be above the middle of the pons in order

that there may be paralysis of the face and limbs at the same time.

Dr. Francis Dercum believed that the supposition of some lesion of the cortex going on slowly and leaving a sclerotic patch, and followed by degeneration involving these so-called sweat centres might explain the case. As regards unilateral sweating, he observed it for four or five years in a case which subsequently terminated in apoplexy. No autopsy was made.

Dr. Charles K. Mills said that Dr. Reichert's remarks would indicate a possible cause for this case. It seemed to him that it might be due to a very small tumor or patch of degeneration of some kind high up in the pons. He found, in looking up the subject, one case of unilateral sweating reported in which degeneration of one of the cervical ganglia was found. He attached but little importance to this. He had recently looked up the subject of unilateral progressive facial atrophy, of which more than fifty cases have now been reported. In a majority of these there has been diminution or entire absence of sweat on the atrophic side.

BALTIMORE GYNÆCOLOGICAL AND OBSTETRICAL SOCIETY.

Regular meeting held March 9, 1886.

First Vice-President, H. P. C. Wilson, M. D., in the chair. Wm. E. Moseley, M. D., Secretary.

Dr. P. F. Mundé, of New York, read the following paper:

Ovariotomy During Acute or Chronic Peritonitis.

It has been my misfortune in my experience with the operation of laparotomy for abdominal tumors to meet with the most complicated and unfavorable cases. Thus of sixteen double ovariotomies there were four intra-ligamentous cysts, three of which contained pus and were not removable except by piece-meal; in two cases the walls of the cyst were practically rotten and so friable as to break down under the slightest manipulation; in one case there was a suppurating dermoid cyst with extensive adhesions to the bladder and pelvic wall; and in two cases previous rupture of the cyst, with the production of diffused chronic peritonitis had taken place. Adding to this latter category three cases of single ovariotomy during chronic peritonitis in two of which the peritonitis was due to rupture of the cyst, and in the other to aspiration, and I have had five cases of ovariotomy performed during general peritonitis, one acute and four chronic. Certainly this array of complications does not forecast a high rate of recovery, and in reality it stands at 50 per cent. of double ovariotomies. But I have the satisfaction of knowing that one patient recovered after operation during chronic peritonitis, one after removal of a suppurating dermoid cyst with lesion of the bladder and catgut suture, one after removal of a multilocular cyst weighing fifty pounds, all double ovariotomies, and one after partial excision of a huge cyst of the broad ligament containing 48 pints.

Of my single ovariotomies nearly all recovered. But it is not my object to report here my results in ovariotomy (I must wait until the number of my cases has greatly increased before it is worth while to do this), but to relate very briefly the cases in which I have been so unfortunate as to have presented to me conditions for which I deemed it my duty to operate, and still in which the chances for recovery were next to nothing. I think that from a consideration of these cases some practical deductions for future guidance may be gathered. At all events, I hope to elicit valuable hints from the discussion. I feel it but just to myself to state that in operating upon these, often really desperate cases, I have been actuated by the rule very properly, as I think, laid down for his own guidance by Dr. Goodell, never to refuse to operate in any case which, in his opinion, offered the slightest chance for the recovery of the patient. And, with him, I have thereby no doubt greatly injured my statistics of recovery. But as we usually learn quite as much, if not more, from our failures than we do from our successes, I do not hesitate to report the five cases of ovariotomy during peritonitis, only one of which recovered, feeling that I have nothing to reproach myself for either in venturing to operate or in the after-treatment. As to the justifiability of immediate removal of an ovarian cyst during peritonitis, acute or chronic, as soon as the existence of the latter condition is discovered, there can probably be no question since the brilliant results of Keith, Freund, Veit, Tait, and many others, in operations of this kind. Some of the apparently most desperate cases have recovered after removal of the ovarian cyst and drainage. The peritonitis may be due to two causes—1. The inflammation and mortification of the cyst; and 2, its rupture and the escape of its contents into the peritoneal cavity; and it is on these two points, the diagnosis of the cause and presence of the

peritonitis and the treatment of the cyst contents effused into the peritoneal cavity, that I desire to dwell more particularly. 1. The cause of the peritonitis may be either accidental rupture of the cyst, by violence or spontaneously, the cyst walls having become inflamed or friable by torsion of the pedicle, outside violence, or without known cause. Or, a not unfrequent occurrence, aspiration or tapping of the cyst may have excited inflammation of the sac or peritonitis. The *diagnosis* of acute peritonitis in such cases is based on the general principles on which that condition is recognized. Subacute and chronic inflammation of the peritoneum, however, are more obscure and can be suspected or clearly discovered chiefly by a rise of temperature, with morning and evening exacerbations, a dry furred tongue, quick small pulse, general depression, in fact symptoms similar to those characteristic of typhoid fever. There is some tenderness over the abdomen, which is of course distended if an ovarian cyst is present, but the distention is not so prominent and ovoid as is usually found with that disease. The occurrence of rupture of an ovarian cyst may be surmised from the statement of the patient that at some period more or less remote, a sudden pain was experienced in the abdomen as though something had given way, and that thenceforth she had diffused abdominal pain, fever, and general prostration; further, from the appearance of the abdomen, which is flat, while distended, simulating ascites, with tympanitic resonance over the prominent portions and dulness in the flank, which relations do not change or but slightly on the patient assuming the lateral decubitus. If it were ascites, the area of dulness and resonance would change on altering the position, but the thick ovarian fluid does not shift so easily as the watery ascitic discharge. Besides, there is a boggy, doughy feel of the whole abdomen, different from either ascites or ovarian cyst, and similar to œdema of the abdominal parietes. The umbilicus, which is usually somewhat prominent in ovarian tumors and ascites, remains flat if thick ovarian fluid is scattered among the intestines. A wave of fluctuation is usually not perceptible or very indistinct after rupture of an ovarian cyst, unless the fluid is very thin. Per vaginam only a very diffuse indistinct sense of resistance is felt in the vaginal vault. On bimanual examination no distinct cyst with firm elastic walls is felt, but the experienced diagnostician will detect a flaccid, yielding, boggy mass in the abdomen, which varies in dimensions in accordance with the time allowed the cyst to refill since the last rupture. Only a practiced touch will recognize this peculiar sensation and appreciate its relation to the general condition of the patient.

2. The *treatment* of an ovarian cyst complicated by chronic peritonitis, be the latter due to aspiration or to rupture of the cyst, invariably is laparotomy, removal of the cyst, and cleansing of the peritoneal cavity so far as possible, followed by drainage. There can be no doubt as to the justifiability of this practice; too many operators of the highest eminence have adopted it, and its success as a whole has warranted their action. But as to the treatment of the contents of the cyst which were effused into the heretofore presumably healthy peritoneal cavity, there exists some difference of opinion. While *eo ipso* the only correct treatment would seem to be the immediate careful removal of all the noxious contents of the ovarian cyst from the peritoneal cavity by sponging and irrigation, experience seems to show that drainage will in course of time entirely and safely remove the ovarian fluid (which is often colloid, that is, thick and glutinous), and that no harm occurs to the system by allowing this usually irritating matter to remain in prolonged contact with the peritoneum. In explanation of this apparent immunity it should be noted that the peritoneum doubtless has by chronic inflammation become proof against fresh irritation. My experience warrants me in stating the belief that it is safer to leave the gradual elimination of the effused ovarian fluid (be it thick or thin) to the medium of the drainage-tube than to attempt to remove it manually (if it be stringy and colloid) by prolonged, careful sponging or by copious antiseptic irrigation of the abdominal cavity. I cannot but think that the traumatic irritation of the last procedure and the shock following the irrigation of so large a surface as the intestino-peritoneal area by an antiseptic lotion (particularly bichloride) are more injurious and hazardous than to allow free, voluntary drainage through a tube. I am impelled to this conclusion by the result of a case operated on by Lusk during the past year (reported to me by Polk, who was present at my fourth operation of this kind, and who concurred in the treatment), and another reported by Max Runze (*St. Petersburger Med. Wochenschrift*, 2, January, 1886), in both of which rupture of the cyst took place, an enormous quantity of thick gelatinous matter was found in the peritoneal cavity, which was removed gently so far as

possible, the cavity was then drained and recovery took place. In Runge's case, colloid matter was discharged from the drainage-tube as late as the fortieth day after operation. That the danger of fresh septic infection, of relighting the subacute peritonitis, and above all, of seeing the patient die from shock, stare the operator in the face in such cases can unfortunately not be denied. It is a question simply of leaving the patient to a certain and lingering death or of giving her the chance of recovery by an operation, the results of which have been often most favorable. My own individual results should be no criterion, since my cases have been exceptionally difficult and unfortunate. After these preliminary remarks, which have attained a length quite unintended, I will give a brief report of my five cases of ovariotomy during peritonitis.

Case 1. Æt. 33; single; November, 1875; apparently unilocular cyst; abdomen exceedingly tense. Operation refused. In order to gain time and to relieve tension, aspiration with fine needle under antiseptic precautions. Removal of the chocolate-colored fluid. About a week later high temperature and symptoms of subacute peritonitis. Ovariotomy, November 14; patient, with pulse 120, temperature 99.5°, exceedingly prostrated. Cyst entirely removed; peritoneum studded with flocculent lymphatic adhesions and deposits. Drainage. Death on sixth day from septic pyemia, the right parotid gland showing probable metastatic enlargement and suppuration. Earlier operation might have saved this case.

Case 2. Mrs. F., forty-four years, multipara; large—apparently solid—tumor. Operated on March 10, 1881; colloid matter escaped on opening peritoneal cavity. A large multilocular tumor adherent to bladder and intestines. Fully fifty ligatures were applied; thorough syringing; no drainage. Recovery without a bad symptom. Weight of tumor, thirty-five pounds.

Case 3. Mrs. S., thirty-eight years; single; was seen by me in September, 1883; lived in a farm-house in New Hampshire, seventeen miles from Hanover. Evidently in a septic condition. Double ovarian tumors. Advised removal as last desperate chance. Accepted. Day appointed for operation about one week later. Drove out with assistants and found patient greatly weakened by vaginal hemorrhage the night before. I discountenanced the operation, but she insisted upon it. Pulse 130, temperature 102°. On opening the abdominal cavity, gush of colloid and purulent matter; general chronic peritonitis. Right tumor largely adherent; left intra-ligamentous, rotten and removable only by piece-meal. Death of patient while inserting abdominal sutures.

In this case I should never have consented to operate, but for the urgent request of the patient and the fact that I had come so long a distance to do the operation. Had the second tumor not been intra-ligamentous and so difficult of removal, I firmly believe that I could have at least removed the patient from the table alive.

Case 4. This was the most interesting and instructive of all my cases. The patient was a multipara, who, in August, 1883, had a fall on the abdomen, and then noticed an abdominal enlargement, with severe pain, both of which had increased since. The abdomen was found, in March, 1884, when I first saw her, to be flat, with projecting sides, dull on percussion, indistinct fluctuation, which remained unaltered on changing the position of the patient. On the right side a loose flaccid mass could be felt. Aspiration was performed, but nothing obtained. On the left side deep in the pelvis was found a tumor of the size of a cocoanut, with tense walls. Diagnosis of rupture of ovarian cyst of right side (probably colloid on account of absence of fluid by aspiration) and of intra-ligamentous cyst of left side, was made and early operation advised. But as patient still felt pretty well, she decided to wait. Three weeks later she returned very much worse and desired immediate operation. Temperature 103°. On opening the peritoneal cavity, colloid, stringy matter escaped in enormous quantity, and it required careful manual efforts to remove even a semblance of all the effusion, which reached from Douglas's pouch to the diaphragm. It seemed to me, and to those who assisted me, imperative to remove as much of this supposed toxic material as possible, and I finally decided to irrigate the abdominal cavity with a 1 to 2,000 solution corrosive sublimate, with the patient on the side. The colloid matter came from a cyst of the right ovary, as diagnosed three weeks before the left cyst was enucleated, and proved to be full of fœtid pus. The colloid matter removed weighed thirteen pounds. The highly prostrated patient died of shock twenty-two hours after operation. I feel fairly confident that if I had allowed the colloid matter to find its way out of the peritoneal cavity gradually through a drainage-tube, under proper antisepsis, the patient would have stood a far better chance of recovery, as did those of Lusk and Runge.

Illustrations of Exceptional Symptoms and Examples of Rare Forms of Disease.

Mr. Jonathan Hutchinson thus writes in the *Brit. Med. Jour.*, July 10:

Recovery from Ascites, after Paracentesis, in a Young Man, the Subject of Disease of the Liver; Good Health Seventeen Years Afterwards.

I saw, with Mr. Alfred Kennedy, at West Ham, in May, 1884, a case of very considerable interest in reference to prognosis. Our patient was a man, named G., now aged 35. The reason for my seeing him was that he had been recently injured in a railway accident, but the interest of his case belongs wholly to his former history. Seventeen years ago, when he was 18, he had a long illness which, he said, was diagnosed as "ascites, pleurisy, and diseased heart and liver." He was treated in St. Thomas's Hospital, under the care of Dr. Bristowe. Some scars under the umbilicus confirmed his statement that he was tapped more than once for ascites. The left side of his chest was decidedly contracted. Both legs were covered by dusky stains, as if he had formerly suffered from thrombotic purpura. His heart's action was very irregular. I could not detect any *bruit*, and there was no proof of hypertrophy, but the action was peculiar and jerky, possibly from adherent pericardium. I was told that on some occasions a murmur had been detected. His liver was still very much enlarged; its edge, thickened and bossy, could be very easily felt two inches below the ribs; it appeared to be equally enlarged in all parts. The man told us that he had enjoyed excellent health, in spite of the conditions mentioned, ever since his discharge from St. Thomas's Hospital. He had never had any return of the ascites or œdema of the legs. He had led an active life, and had only suffered from a little shortness of breath and palpitation, after making unusual exertion. He had been married for six years; he looked fairly healthy, but not robust. Since the railway accident, he had suffered from palpitation, with a tendency to faintness and to hysteria. There did not appear to be any definite explanation of his former illness, for he alleged that he had always led a temperate life.

Having forwarded the above narrative to my friend Dr. Bristowe, he was so very kind as to refer to the hospital records, write out the following notes, and permit their publication:

Dr. Bristowe's Notes.—"G. G., aged 20, came under my care in St. Thomas's Hospital, November 11, 1869. The history he gave was to the effect that, two years previously, he had been laid up for three months in University College Hospital with pleurisy, from which he had recovered; that, three months later (eighteen months ago), he began to complain of swelling and tenderness in the epigastric region, and that, from that time, he had been gradually enlarging in the abdomen. He continued at work up to three weeks ago.

"On admission, he was pale and thin. The abdomen was large, containing so much fluid that only a very small area of resonance existed in front. There was no tenderness, and no definite enlargement of liver or tumor to be detected. The left side of the chest was much contracted, measuring, at the nipple line, only 16½ inches in circumference (the right measuring 18). It was dull in its lower half, and the breath-sounds were feeble or absent; no cough; no signs of progressive disease; urine free from albumen; legs œdematous. In other respects he was healthy. The abdomen slowly increased in circumference (at level of navel) from 38 inches to 41, and, on January 6, two months after admission, twenty-three pints of fluid were removed by paracentesis. He was relieved, but slowly refilled, until, on March 7, twenty pints were removed. After this he appeared to be filling again slowly, and he left the hospital on April 11, still presenting some ascites; but his general health seemed good.

"I have no record of his occupation, or of his habits, or of any statement with respect to syphilis;* and I never detected clear evidence of disease of the liver. I have not recorded my diagnosis; but I suspect that I attributed his affections, first, effusion into

*The notes from which I quote are in my own handwriting, and I believe that the absence of reference to these points means that I elicited nothing worthy of record or that seemed to throw light on the nature of his case. My notes are difficult to read. On looking through them again I find that after each tapping I examined the abdomen; that, after the first, I did not recognize hepatic enlargement; but that, after the second, I remarked that there was dulness for two inches below the right ribs, and that, in the scrobiculus there was a distinct hard edge, feeling like that of liver, but moving with the abdominal walls.—J. S. B.

the pleura, and then ascites, to tuberculosis. During the greater part of his residence in hospital, he was treated with quinine and iron. There was no disease of the heart."

Simulation of Brachioplegia by Rheumatism.

When the patient to whose case the following statements refer entered my room, with his head bent forwards and his arms held stiffly by his sides, I certainly thought, as he did, that it was a case of incomplete paralysis of the upper extremities, probably consequent on an injury to the cervical spine; and it will be seen that the history which he gave was one which quite fitted with such a diagnosis. He said that his arms were powerless immediately after a fall from a swing, and that they had remained so ever since. On careful examination, however, I came to the conclusion that nothing had happened excepting a severe contusion of the neck and shoulders, causing pain in motion, and that the enforced rest, subsequently, had induced rheumatic stiffening of both shoulder-joints. On careful inquiry, it appeared that at no time had there been any sensory paralysis. There had never been any numbness in the limbs, or "pins and needles." Although all the muscles were wasted and thin, none were especially so, excepting the deltoids. He could move all the joints of his forearms, hands, and fingers, quite well. The deltoids were so wasted, that all the bony prominences were easily seen. Both shoulders were stiff, permitting only the very slightest degree of motion; in both, there had been much aching, especially about the insertion of the deltoid, as usual in cases of rheumatic disease of the joint.

I inquired whether there was any tendency to rheumatic gout in his family, and found that his father had had gout, and that he himself had suffered from lumbago. From the manner in which he held his head stiffly forwards, and from his complaint of pain in the back of the neck and shoulders, it seemed probable that rheumatic changes were in progress in the joints of the vertebræ, tending to the production of spondylitis deformans. It is possible that he may have had some fracture of the laminæ; but, whether this occurred or not, it is clear that there were never any real indications of injury to nerves. After the fall, he had much pain in the neck, and could not use his arms. He could walk, and was able to ride home, and walked upstairs, holding his arms across his chest and his head bent forwards. He was nearly two months in bed after the accident, with pain in the neck and arms. During that time, he lay almost constantly on his back in one position.

Neuralgia of the Scalp, Probably of Gouty Origin: Detailed Description of the Pain.

A gentleman, possessed of some anatomical knowledge, and almost hypochondriacal in his tendency to self-observation, described to me the following symptoms: Early in the morning of March 2, he experienced over the middle of his left parietal bone a sharp explosion of lightning-like pain. It began exactly in the middle, and passed forwards nearly to the forehead, and backwards nearly to the occiput, being most intense in the centre. It radiated a little laterally, but not nearly so far as it went backwards and forwards, and it never crossed the middle line. It did not run in straight lines, but spread out somewhat like a coruscation of sheet lightning. It was over in a few seconds, but quivered a little, not being absolutely momentary. After one explosion, another, and often a third or fourth, would follow in quick succession, and then he would be quite free for half an hour or an hour. The scalp was not in the least tender. The pain was quite bearable; in fact, at first it rather amused than hurt him; but, as the day went on, it became worse, and the explosions were attended by a feeling as if the left half of the head were being suddenly crushed. In the evening, the explosions were both more frequent and more prolonged. On some occasions, there was the suggestion of a pain passing into the cheek and lower jaw, involving, in fact, the whole half of the head; but, in these parts, its course could not be traced with accuracy. Neither in the upper nor in the lower jaw did it run along the course of known nerve-trunks. The bicuspid tooth of the lower jaw was aching a little all day; but it was a steady ache, attended with a feeling of general numb swelling about it, and with tenderness on pressure, which prevented eating, but without any explosions of severe pain. My friend became very nervous in the evening, feeling sure that he was about to be the victim of "tic-douloureux."

I found that, on the previous day, he drank a bottle of claret instead of his usual modicum of a third; that he had eaten much more liberally of meat than was his wont; and that, on the day on which his neuralgia began, he also felt his ankles and wrists puffy and aching; and, finally, that his urine began on that day to deposit uric acid freely.

Knowing that he had for long been threatened with gout, I assured him that the neuralgia was gouty, and made him take a full dose of bicarbonate of potash at bedtime. On the next morning, both the toothache and the sheet-lightning pains in the head had ceased, and nothing remained but a very slight perception of general ache in that side of the head.

Although it is easy, in this instance, to feel confident as to the influences which were at work, and to say that the neuralgic shoots, and probably the toothache also, were caused by a gouty state of the blood (lithæmia), yet it is more difficult to explain the local mechanism of the pain. The scalp-pain always began in one and the same spot, and that not one to which any anatomical peculiarities attach. Was it a periosteal pain, and due to changes (neuritis?) in some ganglia, or other peripheral nerve-organ? Such seems the most probable hypothesis.

I could sympathize much with my patient, having often experienced pain of a somewhat similar kind. From my own observations, I can quite confirm the accuracy of his distinction between pains which are like forked-lightning, and those to which the comparison of sheet-lightning may be applied. The latter are less severe, as a rule, and always less momentary than the others. They spread over a wider area, and do not feel to run in such straight lines. Both of them differ from another kind of explosive pain, in which the shoots extend for equal distances around the centre of starting. This might be called the star-shaped pain, or bomb-shell explosion; but, if the latter term be used, it must be clearly understood that the pain denoted, although always radiating, is by no means always of any terrible degree of severity.

Irreducible Prolapse of the Rectum Treated by Amputation; Recovery.

Mr. O'Connell Raye thus writes in the *Lancet*, July 10:

A Hindoo male, aged forty-four, was admitted suffering from prolapse of the rectum of several days' duration. The protruded parts were livid and ecchymosed, with here and there isolated patches of sloughing mucous membrane. The mass was about the size of the clenched fist. The patient was in great suffering and much exhausted. He was placed under chloroform, and careful, prolonged efforts were made to reduce the prolape, but without success. The measures commonly recommended for the relief of irreducible prolapse—such as excision of strips of mucous membrane, scoring with the actual cautery, nitric acid, etc.—seemed scarcely suitable for this patient, as the bowel had been protruded for several days, and was in a very doubtful state of vitality. Mr. Raye therefore resolved to amputate the protrusion level with the encircling skin. He acknowledged that he should almost certainly have to open the recto-vesical pouch, but hoped, nevertheless, to be able to keep the peritoneum free from contamination. The parts were carefully examined lest they should contain a loop of intestine.

For the operation a Wood's hernia needle was used, armed with a stout silk ligature about two yards long. The needle was introduced along the left index finger within the protruded bowel as far as the level of the anal orifice. The point of the needle transfixed the protrusion from within, and emerged on a level with the skin. A loop of the silk was caught, and held while the needle was withdrawn within the lumen of the bowel. The bowel was again transfixed on the same level, with the needle still threaded, so that the point emerged on the external surface of the prolapsed rectum about one inch away frem the first puncture. Another loop of the silk was there similarly caught and retained. This procedure was repeated, just as in the ordinary method of ligaturing a nævus in sections, until the entire mass was included. The external loops were then cut and tied, and thus each included portion was separately secured, The next step was to amputate the mass. Expecting to meet the pouch of peritoneum, Mr. Raye began in front by carefully cutting until he came upon this structure. He dissected the pouch from its surroundings in the manner employed with the sac in some of the modern operations for radical cure of hernia. When the pouch was thus secured, it was raised out of the way and the prolapsed rectum amputated just below the transfixing ligatures. There was no hemorrhage. Two of the ligatures had transfixed the pouch. He divided these two ligatures, and as portions of the cut edges of the bowel were thus liberated, these edges were seized with Spencer Wells's clamp forceps to prevent bleeding. The prolapsed recto-vesical pouch, being now free, was drawn gently downwards a little, and its neck tied with carbolized catgut just above the point where the ligatures had passed through it. The sac was then cut off, and its pedicle allowed to slip back within the pelvis, secured by the catgut ligature. Those portions of the cut

edges of the bowel which were held in the clamp forceps were again transfixed with ligatures, which, when drawn tight, completely occluded the orifice through which the process of peritoneum had been protruding. The ring of ligatured bowel was pushed within the anal orifice, the ends of the silk ligatures hanging out for facility of removal; a morphia suppository was inserted, and the man put to bed. The operation occupied about three-quarters of an hour.

There was considerable pain for two days. On the third day the bowels were moved naturally. From the first there was no difficulty in micturition. Two ligatures were found loose on the twelfth day. Two more ligatures came away two days later on. By this time the patient felt quite well, had little or no pain on defecation, and had complete control over the action of the bowels, from which it was presumed that some portion of the sphincter remained. The calibre of the bowel was almost normal, a ring being felt where the ligatured portion lay about an inch within the anus. Whether this ring disappeared subsequently by absorption, or whether it contracted to form a stricture, Mr. Raye is unable to say, as the man absconded on the twenty-first day, some of the ligatures being still *in situ.*

A New Operation for Ptosis.

Of late years several attempts have been made to improve upon the old operation for congenital or paralytic ptosis, which merely consisted in removing a fold of skin from the lid. The principle of the operations of Dransart and Pagenstecher is to establish a connection between the lid and the occipito-frontalis muscle by means of subcutaneous cicatricial bands, got by allowing sutures to ulcerate their way out along their tracks underneath the skin. Panas (*Archives d' Ophtalmologie,* vi. 1, 1866,) has found the following operation very successful, and not followed by so much pain and swelling as Dransart's, of which, however, he admits the efficiency. An assistant applies his hand to the patient's forehead to prevent the drawing down of the skin of the lid, by which the natural arrangement of the tissues would be interfered with, and the precision of the necessary incisions affected. He first begins an incision along the line of the upper border of the tarsus. This incision is, however, not continued along the whole of that line, but interrupted so as to leave a central portion of one-third inch in extent uncut. A second horizontal incision, with a slight convexity upwards, and not quite an inch in extent, is made in the position of the fold of separation between the eyebrow and lid, and therefore about over the orbital margin. The second incision must involve all the tissues down to the periosteum, and by means of two short vertical incisions be joined with the inner extremity of the external portion and outer extremity of the internal portion of the lower incision. Finally, a third incision is made parallel to the second, and somewhat more than an inch in length, along the upper border of the eyebrow and passing down to the periosteum. The little peninsula of skin and muscle included between the middle and lower horizontal and the two vertical incisions is next dissected free from the tarsus down to its ciliary border, taking care not to interfere with the suspensory ligament of the lid. The bridge between the middle and upper incisions is then undermined, whilst avoiding periosteum and suspensory ligaments. When this has been done, the dissected flap is pressed up underneath the undermined bridge, and attached by three sutures to the upper edge of the upper incision. To prevent the traction on this medial flap producing ectropion, a suture is put in at each side, by which means the conjunctiva and suspensory ligament of the lid are united to the edges of the upper incision. Panas claims in this way to have introduced an operation which meets the indications required by a shortening of the lid to the desired extent by the raising of its tarsal portion, and causing the insertion of the occipito-frontalis muscle to occupy the position and assume the function of the absent or paralyzed levator.

Cocaine for Burns, Blisters, etc.

Before the Richmond Medical and Surgical Society, Dr. Landon B. Edwards said that he wished to emphasize the special value of cocaine in the treatment of *burns.* Recently he was called to a lady who had turned over a kettle of boiling water on one of her ankles and foot. When he arrived, the blisters that were unbroken apparently contained as much as three gills or more of serum, and the lady was suffering intensely. A number of the blisters were broken in removing her stocking. She was wearing very low-cut house-slippers at the time of the accident. She wanted something "to take the fire out." He had with him two drachms of a four per cent. solution of cocaine muriate (gr. v. to ʒij of water) which he applied with a camel's hair pencil to th

raw surfaces, and around the margins of the raised blisters. In twenty or thirty minutes she was easy. He then prescribed:

℞. Muriate of cocaine, ℈iv.
Distilled water, ʒiv.
M. S.—Apply enough to wet the raw surfaces when painful.

The pain was kept constantly relieved by these applications, made at varying intervals of from two to six hours. The next morning the lady put on her stocking—which broke other blisters—and poured the solution on it over the injured parts. Thus, against advice, however, she went about her house attending to household duties, and said she didn't need the doctor. In a few days she was thoroughly well, with some slight cicatrices. He spoke also of a cook who severely burned her arm, which he treated in pretty much the same manner, and with like good results. He further mentioned the case of a book-keeper, who by boat-rowing severely blistered his hands. The raw surfaces in the palms, due to the breaking of the blisters, were so painful as to prevent the use of the pen or handling his books. By keeping the sores painted with a three per cent. solution of cocaine, he was able to attend to his duties without pain. In many like injuries cocaine is extremely serviceable, and we should keep it at the head of our lists of "ready-relievers," in cases of cuts, abrasions, etc.

Cardiac Neurosis in Connection with Ovarian and Uterine Disease.

Dr. H. J. Boldt thus concludes a paper in the *American Journal of Obstetrics* for August:

There are a large number of patients afflicted with uterine or ovarian disorders who also suffer from nervous heart affections, and some cases who give only a history of the latter, in whom this will be found dependent on the former disorder, as is well illustrated by example No. III. The symptoms of the affection do not differ from the cardiac neurosis dependent on other causes.

It is necessary to make a careful examination, in justice to the patient, of the reproductive organs, if no other *positive* cause can be found to account for the neurosis.

That grave organic lesions may be suspected by only a superficial examination, when the condition is but a nervous imitation of disease, is well illustrated by numerous citations of cases. Flint's* case is a good example. When the neurosis is due to ovarian lesion, it is usually the left ovary which produces the mischief, as has already been pointed out by Dr. J. Milner Fothergill, and coincides with my own observations.

In conclusion I would say that the cases cited were such in which the reflex cardiac neurosis caused the greatest inconvenience to the patients when they presented themselves for treatment; and that an argument that treatment for the neurosis directed to other organs than the pelvic, would in these cases not hold good, as they were thoroughly tested previously; also that the observations are not confined to a few patients, but extend over a series of nearly two thousand patients taken as they came, after beginning my own investigation, and it is from this list that I take my per centum.

* Pepper's "System of Med.," vol. iii., p. 750.

The Treatment of Rabies with Hoang-nan.

According to the *Gazette Médicale de Nantes*, twenty-four cases of rabies have been treated with hoang-nan by Dr. Barthélemy and several other medical men of that city or of the department. The first case so treated was in the month of March, 1882, the last in April, 1885. Ten times, at least, the bites, which were most frequently multiple, were situated on the hands, once on the hand and on the face. In the majority of cases cauterization was completely omitted, or practiced several hours, or even several days after, with agents little active, such as liquid ammonia or a solution of carbolic acid. Two of the patients, who were closely observed by Dr. Barthélemy—viz., a man of thirty and a lad of sixteen—presented symptoms of rabic mania: persistent insomnia, anxiety, nocturnal agitation, the desire to run, hallucinations, barking, etc. However, none of these persons felt hydrophobic, nor have any of them, to this date, succumbed. The duration of this preventive treatment was, on an average, twelve days. The total dose of the powder of hoang-nan ingested during this time, varied in adults from six to eight grammes. It was scarcely necessary to go beyond one gramme per day to obtain the physiological effects of the medicine—exaggeration of the reflexes, cramps, rigidity, slight trismus. The maximum dose was arrived at progressively, and in some cases the treatment was terminated by gradually decreasing doses. From the above cases the author deduces either that rabies is communicated much more rarely to the human species than is generally admitted, or that the hoang-nan, administered progressively to the physiologi-

cal effects *during the period of incubation*, sufficiently and efficaciously modifies the nervous system and the entire economy to prevent the evolution of the rabic virus.

A Peculiar Accident Following an Operation for Hydrocele.

MM. Boursier and Loumeau relate the following case in the *Journal de Médecine de Bordeaux*, of June 20, 1886:

A strong, healthy man, aged 44, of good antecedents, and presenting no history, hereditary or personal, of nervous troubles, entered hospital on account of a hydrocele. There was nothing peculiar to note about the hydrocele, which occupied the right side of the scrotum, and upon which it was decided to operate by evacuation of the fluid and injection of dilute tincture of iodine. Immediately upon the injection of the first few drops the patient complained of pain in the cord and groin, and of cramps in the right forearm. The hand was seen to be slightly flexed toward the ulnar side, the little and ring fingers were completely flexed, while the middle finger and index had their two terminal phalanges extended on the first, this one being flexed on the metacarpus; the thumb was flexed and drawn toward the other fingers. In a short time the same convulsive movement took place in the left hand. There were neither convulsions nor syncope, but the painful contractions persisted for some minutes, and then gave way, the index and middle finger becoming completely flexed, the hand also being flexed on the forearm. On a question being addressed to the patient it was found that he could not articulate, the muscles supplied by the hypoglossal being also contracted. The latter soon disappeared, but the contractions in the forearms and hands persisted for nearly an hour. The authors regarded the spasms as of reflex origin, but were unable to explain their localization to the muscles supplied by the median, ulnar, and hypoglossal nerves.

Habitual Miscarriage Successfully Treated with Tincture of Chloride of Iron and Chlorate of Potassium.

Dr. W. J. Strother thus writes to *Gaillard's Medical Journal:*

I send you a report of an interesting case occurring in my practice; not claiming any credit to myself, however, for the plan of treatment adopted, as I had seen the report of a similar case and its successful treatment in one of the medical journals.

Mrs. H., thirty years of age, married seven years. Has had six or seven miscarriages, these generally occurring from the third to the fifth month. Hemorrhage would begin about the second month, and recur every four days until the fœtus was expelled.

She had a miscarriage about fifteen months ago, at which I was in attendance. Remembering reading of a case of miscarriage reported as being due to fatty degeneration of the placenta, in which tincture of chloride of iron and chlorate of potassium were employed with success in the succeeding pregnancy, I examined the placenta and found it almost one mass of fat. At the beginning of the patient's next pregnancy, therefore, I ordered the following mixture:

℞.	Tinct. ferri chlor.,	f℥iij.	
	Potass. chlorat.,	℥iij.	
	Glycerinæ,	f℥j.	
	Aquæ,	f℥v.	M.

S.—Teaspoonful three times a day.

She took this regularly almost every day until she was delivered, at full term, of a healthy male child. About the third month she had a slight "show," but the hemorrhage never returned.

Wash-leather Skin.

Dr. P. H. Emerson, in a recent number of the *British Medical Journal*, discusses a peculiar condition of the skin, in which certain metals mark it with dark lines. Dr. Ferrier, in 1879, termed this condition "wash-leather skin." After a careful analysis of fifty cases observed in the wards of Kings College Hospital, Dr. Emerson draws the following conclusions:

1. As a rule, wash-leather skin does not occur in the healthy.

2. It does not occur in many diseases, being observed only four times in fifty cases of illness.

3. It occurs in patients suffering, as a rule, from diseases which directly or indirectly affect either the trophic or the secretory nerves of the skin, such as renal disease, phthisis, erysipelas, and hemiplegia.

4. Silver is the best metal to use for bringing out the marks.

5. It may precede bed-sores.

6. It is of diagnostic value in testing the vitality of the skin, and the site for experiment is the lumbo-sacro-gluteal region.

Dr. Emerson thinks it probable that this peculiar condition of the skin may be the combined result of (*a*) general malnutrition, and (*b*) injury to the trophic fibres of cutaneous nerves from pressure, and consequent changes in the skin due to an hydræmic paralysis leading to degenerative changes.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

VACCINATION WITH ANIMAL LYMPH.

Basing his conclusions upon a large number of observations extending over a period of five years, and also deducing them from the experience of large institutions, where vaccination is compulsory and carried on under the direction of the German government, Dr. Riesel, in Halle, establishes the following as guiding principles in the vaccination with animal lymph (*Deutsch. Med. Zeit.*, July 19, 1886):

The Italian as well as the Dutch method have no advantages whatever; the best is Reissner's procedure, consisting in scraping off the ripe pustule with a sharp spoon under strong pressure, and while stretching the skin to the utmost so as to cause a state of anæmia of the latter at the time the lymph is thus obtained from the animal.

The dry lymph powder, while remaining in full strength for a very short time longer than the fluid lymph, has the disadvantage of forcing the operator always to prepare the lymph fresh each time he desires to vaccinate, a loss of time, especially of great moment in institutions where a large number of individuals have to be vaccinated.

Glycerine, whose property to protect animal tissues against decomposition, has also proved amenable in the preservation of animal lymph, the various manners of employing it for this purpose being but of subordinate importance.

Additions of aseptic material to glycerine lymph are useless in small and hurtful in larger quantities, for in the latter case they also destroy the activity of the virus, while in the first they do not protect.

Animal lymph must be employed in such a way that the operation is performed with a lancet as dull as possible, and superficial, not bleeding, lengthwise scratches are produced by scraping rather than by cutting.

The local phenomena of inflammation which accompany the protecting vaccine pustule, due to animal lymph, frequently appear to the uninitiated as erysipelatous in character, though they are nothing of the kind.

The areola of the genuine vaccine pustule has nothing in common with erysipelas; the first runs a typical concentric course, the second not.

Erysipelas has a period of incubation of from 15 to 61 hours; the so-called early erysipelas is from 16 to 24 hours.

Against accidental infection of the vaccination wound or of the destroyed pustules, animal lymph offers as little protection as humanized lymph.

Cleanliness of the body, the clothing, and the residence of the person vaccinated, and also of the hands and the instruments of the operator, and of the room in which the vaccination is performed, are of the utmost importance, and serve as the only aseptic precautions which can be observed.

In first vaccinations the strict adherence to the rules just mentioned will always be attended with success.

A NEW ACUTE ERUPTIVE DISEASE.

During the last ten years American practicing physicians will often have been not a little puzzled when called upon to make a differential diagnosis between rubeola, morbilli, and scarlatina. We have occasionally seen cases which partly resembled measles and others again which looked more like scarlet fever, while both evinced all the special peculiarities of rubeola. In some of these cases there was no doubt of the disease being rubeola, for the child had already suffered from morbilli as well as from scarlatina.

In this respect an article published by Dr. Nich. Filatow, of Russia (*Arch. f. Kinderheilk*, Bd. vii., H. 4), is of importance and great interest.

F. distinguishes a rubeola morbillosa, that form which is described in systematic works on medicine, and which mostly resembles morbilli, and another variety less known and less frequent, and appearing more like scarlatina: *rubeola scarlatinosa.* This is a special, acute, infectious, and contagious exanthematous disease of its own, which is characterized by an eruption resembling that of scarlet fever, but which differs from the latter by its uniformly mild course, and by the peculiarities of its contagion. The symptoms are identical with that of the mildest contagion; the eruption has a pale rose-color, is confluent, thickly punctated or marmorated, and *never attacks nose, lips,* and *chin.* Temperature 100° to 101°, moderate pharyngeal redness; no angina. Duration of the eruption sometimes but a few hours, generally from 2 to 3 days, and without being followed by desquamation.

The proof for his assertions F. finds first in the analogy of measles "rötheln") rubeola morbillosa), variola, varicella, etc., and next in the fact that he himself observed several cases where children after suffering from the disease were later attacked by scarlatina.

To be sure, his statement cannot be accepted as final. Cases happen where one attack of scarlet fever does not insure immunity against others, and it may be possible that his scarlatinal form of rubeola is simply a modified variety of the latter. Still, we ourselves feel inclined to F.'s view, and await the observation of those whose position as physicians in charge of large children's hospitals give them an opportunity to determine the question.

ECLAMPSIA.

Our knowledge of eclampsia is not yet very great. If an individual, suffering from some demonstrable organic lesion, is seized with convulsions, which, however, do not frequently return after longer or shorter intervals, we call the disease eclampsia. The definition shows that we consider it the same malady as epilepsy, only that in the latter that permanent alteration has developed in the brain which gives rise to repeated seizures.

With such little knowledge of an important and but too often fatal complaint, it is only natural that we welcome any new information. After years of study Dr. Jüegeur, of Berlin, seems to have made an important discovery in this direction. At the July meeting of the Berlin Medical Society (*Deutsch. Med. Zeit.*, July 19, 1886,) Jüegeur remarked that one lesion he had invariably met with in eclampsia, viz., hemorrhage of the liver. It begins at the periphery and thence spreads and is accompanied by destruction of the hepatic parenchyma. In consequence of this latter process small particles of liver-tissue are found in the blood, and their presence may be demonstrated at any time by a microscopical examination of the blood contained in the right ventricle of the heart of persons who died with the disease.

In all fatal cases some fatty degeneration of the vessels of the brain was found, and fat particles had emigrated or given rise to embolism. In individuals with a very moderate amount of adipose tissue hyaline masses take the place of fat.

J. believes that the lesion of the liver is the main point in eclampsia, while to us it seems as if the morbid appearances described seem to indicate a primary affection of the vaso-motor nervous system. In conclusion, we may mention that long since Virchow proved the existence of fat emboli in the kidneys in cases of eclampsia. This is an interesting subject well worthy of further investigation.

GRATUITOUS MEDICAL SERVICE.

One of the greatest evils in the profession to-day in large cities is the abuse of medical charity. We, of course, do not mean to say that those who are honestly unable to pay for it should be denied the benefit of medical treatment; but we do say most emphatically that a large proportion of those who avail themselves of the free services of dispensaries are abundantly able to pay for medical services, and it is only a spirit of contemptible meanness, unworthy of a true man or woman, that induces them thus to accept, as a charity, that for which they are fully able to pay.

The remedy lies in restricting the service of dispensaries to those who furnish evidence that they are unable to pay a physician for his services. Do this, and give the young man a chance.

CONSULTANTS AND GENERAL PRACTITIONERS.

"A medical association is being formed in London, the members of which bind themselves to call into consultation only such consulting practitioners as are known to confine themselves to purely consulting practice."

Every large city in this country should have a similar association. It is a heartless shame for the *ancient* and distinguished members of our profession to engage in active practice for the smallest fees, when, by so doing, they are ruining the prospects of capable and aspiring younger men. When they have wealth and eminence, they should retire from active practice, limit themselves to consultations, and thus give the young men a chance. It can be only a mean spirit of avarice that thus keeps them in harness, when they have every right and reason to be in repose.

Notes and Comments.

Ocular Disturbances Caused by Dental Irritation.

At the recent Ophthalmological Congress in Paris, M. Paul Redard described a number of cases in which dental affections were evidently the source of ocular disturbance, such as glaucoma, amaurosis, amblyopia, and cloudy vision. In asthenopia, without any apparent cause, the teeth should always be examined. M. Gayet mentioned a case in which disturbance was produced by a tooth fixed on a pivot; the symptoms appeared and disappeared according as the tooth was removed or replaced. M. Fieuzal had observed so many of these cases of correlation between ocular and dental affections, that he had urged that a dental clinic should be annexed to the Quinze Vingts Hospital for blind people. M. Suarez and M. Galezowski mentioned similar facts. M. Javal mentioned a series of cases, of an inverse order, in which dental disturbance disappeared after operating for glaucoma.

Iodism Cured by Sulphanilic Acid.

As iodism is one of the unpleasant sequelæ that will, sometimes, interfere with and complicate and even debar the use of the iodides, we should know how to relieve it. The *Medical Chronicle* says that the extremely depressing effect and severe catarrhal symptoms occasionally produced by the administration of iodides, and known as iodism, have been explained by Ehrlich as due to the fact that nitrates in the presence of weak acids set free the iodine, and on this theory he has experimented with sulphanilic acid as a remedy for the symptoms produced. This substance, having a powerful affinity for nitric acid, possibly prevents this reaction, since, when given in doses of 4, 5, or 6 grains, in half the cases the iodism vanished as if by magic. As much as 7 grains has been given. To render it soluble, one part of bicarbonate of sodium is added to the water used for each $1\frac{1}{2}$ parts of suphanilic acid.

Boric Acid Tooth Powder.

For various obvious reasons, a tooth powder that is antiseptic has advantages over one that is not. Hence we give the following, which Dr. A. D. MacGregor (*Brit. Med. Jour.*, July 10,) has used for years:

Boric acid, finely powdered, 40 grains; chlorate of potassium, ʒss; powdered guaiacum, 20 grains; prepared chalk, ʒi; powdered carbonate of magnesia, to ℥j; otto of roses, half a drop. The boric acid in solution gets between the teeth and the edges of the gums, and there it discharges its antiseptic functions; the chlorate and guaiacum contribute their quota to the benefit of the gums and mucous membrane generally; the chalk is the insoluble powder to detach the particles of tartar which may be present, and the magnesia the more soluble soft powder which cannot harm the softest enamel.

Indurated Chancre of the Ear.

A woman, aged forty-two, was admitted into the St. Louis Hospital, under the care of M. Fournier, on November 21, 1885. She

said that at the beginning of September she had noticed a small lump behind one of her ears. This gradually became larger, in spite of poulticing and blistering. On admission, on each side of the auriculo-mastoidean sulcus was a prominent coppery-red mass, with ulceration between the two. The glands behind the sterno-mastoid muscle were enlarged. There were syphilitic erosions on the velum, and some pigmented stains on the body. On November 24, roseola appeared, and an erosive syphilide on the genitals. The woman could give no explanation of contagion, except that her husband might have kissed her behind the ear. On examination of the husband, he was found to be suffering from syphilitic patches of the mouth and tongue, enlarged glands, and roseola.

Traumatic Tetanus Treated by Venesection and Morphine.

At a meeting of the Societatea Medico-Militara din Jasi (the Jassy Military Medical Society) Dr. Acontz (*Spitalul*, April, 1886) related a curious case of a robust trooper who, having received a blow in the hepatic region, instantly fell insensible and remained so for two hours, by the end of which time there suddenly appeared tetanus (trismus). A venesection was performed, and leeches were applied to the hepatic region. Both of these means, however, failed to rouse the patient. He came round only after a hypodermic injection of five centigrammes of hydrochlorate of morphia. The further treatment was expectant. The man improved from day to day, and after a ten days' stay left the hospital quite well.

Syphilitic Chancre of the Eyebrow.

A man, aged forty-two, was admitted into the Lariboisière Hospital, under the care of M. Siredey, for paralysis of the fingers, probably due to lead-poisoning. On examining the skin, he was found to be suffering from a secondary syphilide. The patient said he had not had sexual intercourse for a year, that he had been in another hospital six weeks before, when the doctor there said he had mucous patches on the scrotum and examined the penis, but found no trace of a sore. On examination, an indurated cicatrix was found on the left eyebrow, and the corresponding pre-auricular gland was enlarged. Afterwards, syphilitic erosions appeared in the mouth. The man stated that, during a quarrel three months previously, he had been bitten by his antagonist on the left eyebrow.

An Enormous Tumor.

The great size of a tumor will often cause a patient to hesitate about consenting to its removal, for in his eyes the danger is in proportion to the size. Of course we know that this is not so. In the *Central. f. Chirurg.*, Dr. W. Stankiewicz reports the case of a patient who had a tumor in the lumbar region, which had been growing for fourteen years and was of such a size that it hung down to the knees. Its base was forty-four inches in circumference. It was removed by operation, and weighed, after extirpation, forty pounds. Unfortunately the result is not stated, so that we are left in the dark as to the effect of the shock to the system of the removal of so large a growth.

To Prevent Mammary Abscess.

Although Dr. Goodell ridicules the idea of *aborting* mammary abscesses, which he does not think can be done, yet Mr. Miall (*Brit. Med. Journal*) says that when mammary abscess is on the point of forming, he has frequently seen all the symptoms rapidly disappear in a few hours, under the influence of fomentations with hot water and carbonate of ammonia. He uses an ounce of the carbonate in a pint of water, and when solution is accomplished the temperature of the fluid will be hardly too high for fomentation to be commenced, with cloths dipped in the liquid. He applies them for from half an hour to two hours, at the same time protecting the nipples. He has often had immediate relief, and seldom requires to make more than three applications.

Serious Oral Bleeding after a Leech.

In the *Vratch*, No. 12, 1886, p. 214, Dr. E. N. Mikhnevitch describes the case of a middle-aged, moderately nourished, non-hæmophilic peasant woman, who was brought to him with all the usual symptoms of severe acute anæmia, and with incessant spitting of blood. According to her statement, having suffered for three days from toothache, she applied a leech to her gum. The leech fell off, but since then (more than twenty-four hours) the wound was bleeding profusely all the time, in spite of the use of cold and a solution of perchloride of iron. The hemorrhage was immediately arrested by plugging with styptic cotton-wool (*gossypium ferratum*).

Blood Changes in Endarteritis.

It is a somewhat interesting question whether the blood itself is affected by mor-

bid changes in the blood-vessels. Some light seems to be thrown upon the subject by the case which Dr. Simeon T. Clark reports in the *Buffalo M. and S. Jour.* for August. The case was one of "chronic endarteritis," and he says that it proves to his mind that, in endarteritis, changes takes place primarily in the intima of the vessels; and after the blood-making membrane becomes somewhat generally affected, the blood itself becomes a changed fluid, tending to deposits, clots, thrombi, pigmentary immigrations, and even exudates of adventitious products.

Phlebotomy in Puerperal Eclampsia.

In a paper before the Clinical Society of Maryland, Dr. Wilmer Brinton, of Baltimore, describes several cases of puerperal eclampsia. His principal reliance was upon the lancet, and the results were satisfactory. The late Dr. Isdell, of Dublin, published, many years ago, a pamphlet in which he advocated phlebotomy in eclampsia, and enumerated a number of cases in which he got the best results. Many of Dr. Isdell's cases occurred in strong countrywomen, and probably the same success would not have attended similar treatment of city women.

Quinine in Whooping-Cough.

This is not a new recommendation, but cumulative evidence serves to entitle it to an estimable place in our consideration. Dr. Ernest M. Lyon, of Newark, N. J., writes to an exchange that he has used it extensively and successfully in his practice, as follows:

℞. Quiniæ bisulph., ℥j.
Elix. simplic. rub., U. S. P., ℥jss.
M. Sig.—Teaspoonful to a child aged five years and upwards.

He gives it every three or four hours until cinchonism ensues, and keeps the patient under its influence, his guide for its administration being the frequency and severity of the paroxysms.

Subpreputial Medication.

The *Medical World* claims advantages in the treatment of gonorrhœa by what is termed subpreputial medication. The method consists in rubbing up morphine and cocaine in lanolin (wool-fat), and inserting it under the prepuce after thorough cleansing. Dr. Taylor claims that this at once relieves all pain by producing complete numbness of the whole organ. He claims that the advantage of lanolin over other vehicles is the readiness with which it is absorbed.

Fatal Effect of Collodion in Small-pox.

M. Comby related a case before the Société de Chirurgie of Paris of a woman suffering from small-pox, and whose face was covered with a solution of collodion to avoid the cicatrices. The eruption was at first retarded, but soon diffuse suppuration took place under the collodion, and the face was converted into a vast suppurating sore, as that which is seen usually after a burn. The patient succumbed after a few days in great pain and high fever, and the post-mortem revealing nothing abnormal, death was attributed to the topical application.

Calabar Bean in Epilepsy.

Herr Rush, of Fritslar, recommends Calabar bean in epilepsy, in cases where other drugs have failed. He records some successful cases in the *Deutsche Med. Zeitung:*

℞. Ext. Calabar bean, gr. 7½.
Spirit etheris, ♏ 80.
Aq. menth. pip., ♏ 300.

Five to ten drops three times a day for children; eight to fifteen for adults. For children he begins with five drops, and increases the dose by one drop daily until the maximum of ten drops is reached. He then diminishes the dose by one drop daily until the initial dose is reached.

It may be tried, but we doubt (from experience) its efficacy.

Treatment of Bruises.

The *St. Louis Med. and Surg. Jour.* says that for bruises there is nothing to compare with the tincture or a strong infusion of *capsicum annuum* mixed with an equal bulk of mucilage of gum-arabic, and with the addition of a few drops of glycerine. This should be painted all over the bruised surface with a camel's hair pencil and allowed to dry on, a second or third coating being applied as soon as the first is dry. If done immediately after the injury is inflicted, this treatment will almost invariably prevent the blackening of the bruised tissue. The same remedy has no equal in rheumatic, sore, or stiff neck.

Rheumatic Urethritis.

Rheumatic urethritis is what M. P. Riel (*Lyon Médicale*, March 14, 21, 1866,) names a form of urethritis occurring in the course of rheumatism, accompanied by a discharge of purulent fluid and other symptoms common to gonorrhœa, but differing from it in the complete absence of gonococci. M. Riel depends upon the gonococcus for his diagnosis of specific urethritis. He reports two cases of this form of urethritis, but hesi-

tates to ascribe them solely to the rheumatism, and assumes that there must be certain as yet undiscovered organisms in the secretion to render it purulent.

White Clay in Epididymitis.

According to the *Journal de Med. de Paris*, March 28, 1886, white clay, such as is used by sculptors, has been used in Russia with much success in many cases of gonorrhœal epididymitis.

It is made into a soft mass, spread upon a square piece of linen cloth, and applied to the whole scrotum.

Boskine attributes the therapeutic effect of the *argile*, as it is called, to its refrigerating and metallo-therapeutic properties.

Apone: A New Kind of Pain Expeller.

As we imagine from its counter-irritant action, it would be very likely to relieve pain, we note that the following is said to be the mode of preparation of a sort of pain-killer recommended by Poulet (*Pharm. Zeit.*) under the name of *apone:*

Capsicum	20 parts.
Water of ammonia	10 parts.
Oil of thyme	1 part.
Chloral	1 part.
Alcohol, 60%	100 parts.

Digest the capsicum with the alcohol and ammonia during four weeks, filter, and add other ingredients.

Snuffs for Coryza.

Rabon (*Deutsche Med. Wochen.*) recommends the following powders to be used as snuff in coryza:

1.	Menthol,	2 parts.
	Roasted coffee,	50 "
	White sugar,	50 "
	Mix, and take as snuff.	
2.	Cocaine hydrochlorate,	1 part.
	Roasted coffee,	
	White sugar,	āā 50 "
	Mix, and use as before.	

Treatment of Aphthæ of the Vulva.

Sarazin, in cases of aphthæ of the vulva occurring in children recovering from measles, recommends the following (*L'Union Medicale*, June 26): By means of a badger-hair brush a layer of iodoform to be painted on the inflamed parts, and a piece of lint covered with iodoform to be inserted between the lips of the vulva. The powder is to be removed every twenty-four hours until recovery. Appropriate internal treatment should also be given.

Lotion for Gouty Joint.

Dr. Rothe (*Memorabilien*) speaks highly of the following solution in an attack of acute gout: Liquor plumbi acetat., 15 parts; spiritus vini, 25 parts; tr. opii ammoniat., 5 parts; aq. font., 300 parts. Having first used frequent cold douches, he applies compresses wet with the above solution and covered with mackintosh. The treatment gives great relief from pain, and shortens the attack.

Abortion.

Dr. Fry recently exhibited to the St. Louis Medical Society some bits of rusty wire removed from the vagina of a patient who had aborted at the third month. The patient had been under the care of an ignorant abortionist. Dr. Fry supposed that this man had endeavored to introduce the wire into the uterus, but the wire having become entangled in the cervix, was cut off and left there, after he had in vain endeavored to extricate it.

Application for Warts.

The following formula, a modification of that recommended by M. Vigier for corns, is largely used by Vidal:

℞.	Acid. salicylici,	1 gramme.
	Alcohol, 90°,	1 "
	Ether,	2½ grammes.
	Collodion,	5 "

M. The solution should be painted over the affected surface each day.

Painful Dentition.

The following is said (*L'Union Medicale*) to be an excellent preparation in painful dentition:

Cocaine hydrochlorate,	
Sodium borate,	āā gr. iv.
Syrup of althæa,	♏ 64.
Syrup of poppy to make,	♏ 100.

A little to be rubbed on the gums several times a day.

Catarrhal Headache.

Iodide of potassium is said to quickly relieve the dull headache so often accompanying an ordinary cold in the head. Two grains may be dissolved in a glass-full of water, which is to be taken in little sips during half an hour. Dr. Davis recommends this simple remedy, and says he has hardly ever known it to fail.

Urticaria and Pruritus.

Menthol is said to relieve the itching and

cure the disease. In pruritus ani, and in eczema, the parts should be moistened with menthol solution, containing from five to ten grains of menthol to the ounce of water.

Treatment of Diabetes by Massage.

At the Medical Congress held recently at Wiesbaden, Herr Finkler recommended treating diabetes by massage. He tested this method on a considerable number of patients, and ascertained that glycosuria is lessened by it, even when the patients have a mixed diet. A short time after the treatment begins the patients perspire profusely; they also increase in weight.

Warm Medicated Enema for Acute Menstrual Pains.

For the relief of the violent pains that in some women precede the menstrual flow, Dr. Meniere (*Rivista Balear*) gives a warm water enema containing 30 grains of chloral and 30 grains of bromide of potassium. For young women only half the above quantities should be prescribed.

Glycerole for Cutaneous Pruritus.

R.	Acidi carbolici,	gtts. xv.
	Sodii biboratis,	3 grammes.
	Glycerinæ,	30 "

M. Apply with a brush over the pruriginous surfaces.

News and Miscellany.

Canada Medical Association.

At the nineteenth annual meeting, held in Quebec, August 18 and 19, the following papers were read:

"Keratoscopy as a Means of Diagnosis in Astigmatism," by Dr. Desjardins, of Montreal.

"Tracheotomy in Membranous Laryngitis," by Dr. James Bell, of Montreal.

"Treatment of Tuberculous Glands of the Neck," by Dr. Fenwick, of Montreal.

"Some Details of Uterine and Ovarian Operations," by Dr. Trenholme, of Montreal.

"Excision of the Tarsus in Tuberculous Disease of the Bone," by Dr. Shepherd, of Montreal.

"Evacuation of an Abdominal Hydatid Cyst," by Dr. Kerr, of Winnipeg.

Dr. Kerr reported two cases of "Gunshot Wound of the Hip-joint."

"The Treatment of Acute Purulent Ophthalmia," by Dr. Buller, of Montreal.

"Ainhum," by Dr. Shepherd, of Montreal.

Dr. Fenwick, of Montreal, reported a case of "Amputation at the Shoulder-joint for Myelo-sarcoma of the Arm."

Dr. A. Lapthorn-Smith read a paper on "Alexander's Operation, and the Treatment of Displacements of the Uterus."

OFFICERS ELECTED FOR NEXT YEAR:

President—Dr. J. E. Graham, of Toronto.

Vice-Presidents—For Quebec, Dr. Russell; for Ontario, Dr. Dupuis; for Nova Scotia, Dr. Wickwire; for New Brunswick, Dr. Currie; for Manitoba, Dr. Crowther.

Local Secretaries—For Quebec, Dr. J. Bell; for Ontario, Dr. McKeough; for Nova Scotia, Dr. Trueman; for New Brunswick, Dr. Lunam; for Manitoba, Dr. Kerr.

Place of Next Meeting—Hamilton; Chairman of Committee of Arrangements, Dr. Malloch.

The Population of Paris.

The *London Lancet* says that the rate of increase of population does not appear to be governed by any fixed laws. Paris has only added 16,000 to her population in the course of five years. Is this a matter for congratulation, or the reverse? Looking at the state of poverty in the gayest city in the world, we think that Paris is to be congratulated on her want of fecundity. But, regarded in another light, this slow increase may not be a favorable condition. A population that neither increases nor diminishes may be vigorous and capable of holding its own in the international struggle of existence, but the chances are against this supposition. Excessive fecundity, on the other hand, may not be a spring or sign of strength. Too rapid growth taxes the resources of a nation, and may prove too much for them, thus becoming a source of weakness. A large population of sickly or puny individuals living in a fertile country would soon be exterminated; for unopposed strength knows no peaceful international laws. The slow increase of population in Paris need excite no apprehension if the health of her individuals is not below the normal. Indeed, nothing can be learned from the mere rate of growth of a population as to its state of health. Moreover, we cannot judge accurately of the strength of a nation by the state of its urban population. Fluctuation is rampant in the metropolis of most countries; the numbers may remain the same. Cities are characterized by the presence of the greatest and hardest workers, and any falling out of the

ranks of these is quickly replaced by those who can take their place.

Prehistoric Dentistry.

Dr. Marter, of Rome, has for some time past been devoting considerable time to examining the skulls in the various museums in Italy, and in Etruscan and Roman tombs, and he has given an account of his investigations in the *Independent Practitioner*. In the ruins of one of the Etruscan tombs, about the date 500 B. C., he found a partial denture. It was an arrangement for holding in position three upper artificial teeth by banding them to the adjoining natural teeth. These teeth were carved out of some large animal's teeth. Another denture found in an old Roman tomb consists of two natural teeth fastened by means of soft gold bands to the contiguous teeth. The most recently opened and oldest Etruscan tomb yet discovered in Italy was lately excavated at Capadimonti; this tomb belongs to the sixth century B. C., and amongst several articles of jewelry a denture, very similar to those above described, was found. Dr. Marter was unable to discover any stopped teeth, although many cases of caries and other dental diseases presented themselves. It is certain that dentistry must have been extensively practiced in the early history of the world, and that gold must have been used largely; otherwise the early Greek or Roman legislators would not have mentioned the matter in the celebrated laws of the twelve tables. Law 5th, de Jure Sacrorum, is as follows: "Quoi auro dentes vincti sicut in cum ollo sepelire, se frande esto."

The Brain of Gambetta.

M. Duval (Director of the Laboratory of Anthropology) has recently given to the Society of Anthropology at Paris a detailed description of the external configuration of the brain of Gambetta. He draws special attention to the fact that the cortical structure in the neighborhood of Broca's convolution has become markedly augmented. Usually this part of the brain assumes the form of an M, the two vertical limbs or sulci enclosing a small valve-like portion in the shape of a V. In the brain of Gambetta, however, as has been noted in other cases as well, this V-shaped portion has become doubled on itself, and assumed the form of a W instead of a V. When we recall the fact that Broca, in his memoirs, attributes to this part of the cerebral cortex (left or right-sided, according as the individual is right or left handed) the function of articulate language, the unusual development of this convolution in Gambetta and others confirms, to a certain extent, this opinion now generally accepted. Gambetta was a great orator, his memory for words being most remarkable. He had acquired a rapid and most exact method of expressing his ideas. It, is therefore, somewhat admissible to associate his great oratorical power with this increased growth of cortical tissue in the neighborhood of Broca's convolution.

Medicine in the Middle Ages.

Before the Abernethian Society of London (July 8th), Mr. Henry Power, F. R. C. S., traced the gradual growth of medical science from the Arabic and Greek physicians up to the time of the then learned Spanish schools, and later to those of France, Italy, and Vienna. He showed how the restrictions for the practice of medicine enacted by these schools were far more stringent than in the present day, and especially with regard to the title of Doctor, a subject that was absorbing the attention of the medical profession. He explained that the expense and labor necessary for the attainment of this much-coveted title, would well compare with some of the higher examinations at our universities. The art of medicine, in those days, was in a far more advanced state than that of surgery, the latter being largely in the hands of so-called "specialists," men who journeyed from place to place, advertising in the street-corners their skill, and the triumphs they had achieved. The utterly absurd intricacies of the medical prescription laid the foundation for numerous quack nostrums, a baneful legacy which has been handed down to the present day. The lecturer concluded by remarking what pride each one present must feel in belonging to an institution which could trace its career back early into the Middle Ages, which had raised up men of such eminence, and which had proved such a blessing in alleviating the misery of suffering humanity.

What a Frenchman can do with a Hair.

Of Gen. von Manteuffel, the late German military governor of conquered Alsace, who hated all that was French, it is said that he once, at a public dinner, engaged in a dispute with a French diplomat, who maintained the superiority of the French workmen over the artisians of all other nations. "A thing so ugly does not exist that the skill and genius of a Frenchman cannot

make of it a thing of beauty," he said. Angered by the contradiction, the old soldier pulled a hair from his bristly gray mustache, and, handing it to the Frenchman, said curtly, "Let him make a thing of beauty out of that, then, and prove your claim." The Frenchman took the hair, and sent it in a letter to a well-known Parisian jeweler, with a statement of the case and an appeal to his patriotic pride, giving him no limit of expense in executing the order. A week later the mail from Paris brought a neat little box for the General. In it was a handsome scarf-pin made like a Prussian eagle, that held in its talons a stiff gray bristle, from either end of which dangled a tiny golden ball. One was inscribed "Alsace," and the other "Lorraine;" and on the eagle's perch were the words, "You hold them, but by a hair."

Life Among the Lepers.

We learn from a lay contemporary that the Roman Catholic missionary priest, Father Damen, who has been called the "Apostle of the Lepers," and who, some few years ago, so nobly devoted himself to assuage the terrible misery of the lepers of Hawaii, by voluntarily going to reside in their midst, has himself taken the disease, and is likely ere long to succumb to it. Lady Brassey, in her "Cruise of the *Sunbeam*," it will be recollected, wrote of the visit she paid to the leprosy island of Molokai, which is used as a leper settlement, where all the lepers in the Hawaiian Archipelago are sent, in order that this terrible, loathsome, and incurable disease may be as much restricted as possible, as follows: "In this island are many tiny children, fatherless and motherless; parents without children, husbands without wives, wives without husbands, all condemned to watch the repulsive steps by which each of their doomed fellows goes down to a loathsome death, knowing that by the same road they, too, must pass."

Ice in the Sick-room.

A correspondent of the *National Druggist* writes:

The writer's son suffered with typhoid fever during the heated term of last summer, when the temperature of the room often rose to 90° or 95°, and the patient's temperature ran up to 105° F. and over.

A number of tubs were placed in the room and kept filled with ice, and the doors kept closed. The temperature of the room sank to 80° or less, an average of 12° or 15° below the temperature of the other rooms in the house, and the cooler atmosphere not only added to the comfort of the patient, but aided in keeping down the body temperature, and materially contributed to a final recovery.

We would strongly urge the use of ice in the room as a measure of comfort and luxury for all who are confined to their beds during hot summer days.

Medical Incomes in Canada.

The *Evening Post* quotes from the *Toronto Globe* as follows: "There is only one medical man in this city who last year earned $5,000 from his profession, combined with the interest he received on his previous savings. There is not one man on the list who had $4,000, and only four who touched $3,000. When we come to the comparatively modest and moderate $2,000, we naturally conclude that we shall have a full legion. But no, we have only fourteen all told who came up to this figure. When we come to between $2,000 and $1,000, the number becomes encouragingly large. As many as fifty-one of the best-known and greatly-sought-after doctors of our city are put down under their own hands and seals as having last year lived on from $1,000 to $1,800. Some of these are professors. There remain only the unfortunates who worry along with from $800 down almost to zero. Of these, we are sorry to say, there were last year thirty-six."

Mississippi Valley Medical Society.

At the meeting held in Quincy, Ill., the following officers were elected for the ensuing year:

President—I. N. Love, M. D., St. Louis.

First Vice-President—Joseph Robbins, M. D., Quincy.

Second Vice-President—Jacob L. Geiger, M. D., St. Joseph, Mo.

Third Vice-President—T. B. Harvey, M. D., Indianapolis.

Secretary—J. L. Gray, M. D., Chicago.

Treasurer—A. H. Ohmann-Dumesnil, M. D., St. Louis.

Assistant Secretary—Edward Alcorn, Houstonville, Ky.

The Editor's Work.

The *Courier-Journal* says that some people estimate the ability of a periodical and the talent of its editors by the quantity of its original matter. It is comparatively an

easy task for a frothy writer to string out a column of words upon any and all subjects. His ideas may flow in one weak, washy, everlasting flood, and his command of the language may enable him to string them together like bunches of onions, and yet his paper may be but a meagre and poor concern. Indeed, the mere writing part of editing a paper is but a small portion of the work. The care, the time employed in selecting is more important, and the fact of a good editor is better shown by his selections than anything else, and that, we know, is half the battle. But we have said, an editor ought to be estimated, his labor understood and appreciated, by the general conduct of his paper---its tone, its uniform, consistent course, aims, manliness, dignity, and its propriety.

The Wonderful Drug Clerk.

The most satirical shot at illegible prescriptions that we have yet seen is the following from the *Medical Age:*

A gentleman received a note from his lawyer which he was unable to decipher. On his way to his office he met a friend at the door of a drug store. The friend, after vainly attempting to read the note, suggested that they step inside and hand it to the druggist, without comment. The druggist, after studying it in silence for a few minutes, stepped behind his prescription case, and in a short time returned with a bottle of medicine, duly labeled and bearing directions. When the gentleman saw his lawyer, he was informed that the note was a notice for him to call at his office between three and four p. m. of the following day. It is a pretty difficult matter to "stick" the regulation druggist.

Americans at the Meeting of the British Medical Association.

Among the Americans registered as present at the meeting, we notice the names of Drs. T. A. Emmet and Fordyce Barker, of New York; J. S. Billings, of Washington; Wm. Brodie, of Detroit; J. R. Chadwick, of Boston; N. S. Davis, of Chicago; Frank Donaldson, of Baltimore; Chas. Warrington Earle, of Chicago; H. O. Hitchcock, of Kalamazoo; F. H. Hooper, of Boston; Howard A. Kelly, of Philadelphia; W. T. Lusk, of New York; Hunter McGuire, of Richmond; R. B. Maury, of Memphis; W. H. Pancoast, of Philadelphia; W. F. Peck, of Davenport, Iowa; S. J. Radcliffe, of Washington; H. P. C. Wilson, of Baltimore; Jas. C. Wilson, of Philadelphia; and W. Gill Wylie, of New York.

Medical Novelists.

The *Boston Med. and Surg. Journal* remarks of this class of writers: Sir Henry Thompson is among the noble army of the medical novelists, or, as we might almost say, has gone over to the majority. The neurologist novelists have a fund of experience in their specialty which is often available for the purposes of fiction. But what Sir Henry finds in his specialty to adapt for such ends, is a matter of curious conjecture. The title of his latest work is announced as "All But." Theories are rife among those who have as yet failed to obtain the book, as to whether the plot turns on a case of defeated catheterization, or of the persistence of residual fragments after a lithotrity.

The "Quack" Convention.

The *St. Louis M. and S. Jour.* says that one of the most amusing things in connection with the welcome given the members of the American Medical Association by the citizens of St. Louis generally, was a window piece gotten up by Frazer, the Candy Man, at 609 Olive street. He obtained a large number of young ducks, had their skins stuffed and mounted, and seated them in chairs in a little amphitheatre. The desk in front of each was marked with a parody upon some quack nostrum, and advertisements of patent remedies graced the walls. Among the delegates was a black duckling, labeled "hoodoo." The whole was entitled "The other Convention." The hit was palpable, and enjoyed by the visiting medicos.

To Distinguish Oleomargarine from Butter.

J. Horstler recommends the following procedure: A piece of oleomargarine the size of a hazelnut is placed in a test-tube, and the end made air-tight. Into another test-tube a like quantity of butter is treated in the same way. When both test-tubes are held in the hand, the oleomargarine soon liquefies, forming a clear solution; whilst butter requires double the time for solution, and when dissolved is not so clear as the oleomargarine solution. When the tube is filled one-third full with ether, the oleomargarine is easily dissolved, and does not produce any turbidity or precipitate on the addition of alcohol. Butter when treated in like manner yields a precipitate.

Not a Doctor.

Young Wife—"There is a gentleman in the parlor. dear, who wishes to see you."

He—"Do you know who it is?"

Young wife—"You must forgive me, my dear, but that cough of yours has worried me so of late, and you take such poor care of your health, and—and O, if I were to lose you, my darling!" (Bursts into tears.)

He—"There, there, dear. Your fondness for me has inspired foolish and unneccessary fears. I'm all right; you mustn't be alarmed. But I'll see the physician, of course, just to satisfy you. Is it Dr. Pellett?"

Young Wife—"N-no, it's not a doctor; it's a—a—life insurance agent."

The Best Beef Tea She Ever Had.

A physician prescribed beef tea for a patient, giving the following directions: "Inclose the finely-chopped meat in a glass bottle, then boil by placing the whole in a pot of water." The directions were carried out as far as the boiling the bottle of meat in the pot of water was concerned. But instead of then mixing the finely-chopped boiled meat with the water and giving it to the patient, the lady gave the sick person the hot water in which the bottle was boiled, who said that she hadn't tasted anything so good in a long time.

What New York Drinks.

A recent official report by the New York health authorities states that the Croton water-shed embraces 239 square miles, and has a population of 20,000, with 1,879 dwellings and as many privies, about as many barnyards, pig-pens, and cess-pools, besides cemeteries, graveyards, slaughter-houses, and other sources of contamination, *and with no drainage except by the surface*, which conducts it to the aqueduct. Yet the Croton is the best water supply enjoyed by any large city in America or elsewhere!

Minnesota Opium.

During the year 1885 Emil Weschke experimented on the cultivation of different species of Papaver at New Ulm, Minn., and from the unripe capsules of P. somniferum prepared a quantity of opium which, in the air-dry condition, contained 2.8 per cent. of moisture, and, after drying, yielded 15.230 per cent. of morphine, 0.325 per cent. of narcotine, 0.416 per cent. of codeine, and 3.500 per cent. of meconic acid. The author does not believe that the cultivation of the poppy for the production of opium in this country would be attended with profit.

A New Adulterant of Castor Oil.

A new adulterant of castor oil is being pushed. It is sold to wholesale dealers at 62 cents per gallon for shipment at Cleveland or Chicago, and is known to the trade as "C. C. Castor Oil." The *Druggists' Circular* thinks that it is a heavy, light-colored, neutral mineral oil, worth 20 cents a gallon. Its consistence and density are similar to those of castor oil, but it has a heavy greasy odor and persistent bitter taste. It does not dissolve in alcohol, and in this way can be easily distinguished from castor oil.

An Irreparable Loss.

Railroad President.—"Don't you think that rather exorbitant, Mr. Badger—$11,000 for the loss of your wife and her diamonds in the accident?"

Mr. Badger (indignantly).—"Exorbitant? Well, I should say not. I value the diamonds at $10,000 alone."

A Pair of Centenarians.

There has recently died in St. Petersburg Madame Goruli, a contemporary of the Empress Catherine II., and a lady of the court of the Emperor Paul I. She is stated to have been 114 years old. Among those who attended her funeral was her sister, who had attained the age of 113, but who was still so robust as to be able to follow the bier on foot.

Personal.

—Dr. James R. Chadwick, of Boston, represented Harvard University at the Heidelberg Quinque-centennial.

—The Queen, upon the recommendation of Mr. Gladstone, upon his retirement from office, has conferred the honor of knighthood upon Dr. B. W. Foster, President of the Council of the British Medical Association, and late Member of Parliament for Chester.

—Dr. Wm. C. Dabney, of Charlottesville, Va., has been elected to the Chair of Practice of Medicine, Obstetrics, and Medical Jurisprudence, in the Medical Department of the University of Virginia.

—The *Boston Post* says that "barbers were originally surgeons," and adds, apparently with much feeling, "a great many of them are now."

Items.

—Pasteur is a doctor at last, having been given a degree *honoris causa.*

—In the last five years Billroth has performed operations on the stomach in 32 cases, with 19 fatal results. Out of 15 gastrectomies for cancer, there were 7 recoveries.

—The Kentucky School of Medicine had the misfortune to lose by fire, on June 10th, its entire premises and outfit. It has already secured a new and commodious building, however.

—A correspondent of the *New York Medical Record* says that in Germany the operation for gastrotomy is so common that few care to witness even Billroth's operations for gastrotomy.

—Dr. R. P. Howard having resigned the position of Vice-President of the International Medical Congress, to be held in Washington next year, Dr. J. A. Grant, of Ottawa, has been appointed to the same office by the Executive Committee.

—She was a sweet girl graduate of a female seminary. She had just been married and was preparing to keep house. Some one recommended her to buy some spring mattresses. "Yes," said she, sweetly, "if they are in season, we'd better have some."

—In one of President Cleveland's vetoes he calls attention to the fact that the wound for which a man asks compensation from the government was received while he was engaged in a private pillaging expedition, and was hunted down by the Home Guards.

—"You have large imagination, you ought to write poetry," said a phrenologist to a man whose head he was examining. "I do write poetry," replied the individual, "and the bump of which you are now feeling was caused by a blow from an editor to whom I offered a poem. Please don't bear on so hard."

—"My dear," said a frightened husband in the middle of the night, shaking his wife, "where did you put that bottle of strychnine?" "On the shelf next to the peppermint." "Oh. Lord!" he groaned, "I've swallowed it." "Well, for goodness sake," whispered his wife, "keep quiet, or you'll wake the baby."

—M. Boher, the inspector of lighting in Dresden, has found that the belts even of ordinary steam engines often develop electricity enough to illuminate Geissler tubes and to perform all the ordinary experiments for which electrical machines are used. He thinks that many of the explosions in flouring mills may have been produced by such electricity.

—The habit of some druggists talking to customers while compounding a prescription should be condemned. The habit of leaving a prescription partially prepared to wait on customers is equally reprehensible. Mistakes in putting up prescriptions occur oftener from haste, and trying to do two things at once, than from incompetency.

—During the cholera epidemic in Nashville, Tenn., the late Dr. Bowling attended an old blind negro, who eked out an existence by playing the flute at the street corners. He recovered, and with a heart overflowing with gratitude he took his flute and sat under the doctor's bed-room window and played it the whole night long. Of all the large fees he ever received, the doctor said this was the largest.

"I want some preserves on my bread," whined a boy to his mother. "Johnny," coaxed the mother, "that nice butter and sugar is the thing for little boys." "Wow, wow," he howled, "I won't have it. 'Taint nothing but glucose and oleomargarine, and it's pizen. Gimme preserves if you don't want your little boy to die." He got the preserves.

—A hypercritical medical man found fault with Mary Anderson because of her assuming the stiffness of a corpse immediately on being killed in one of her plays, holding that cadaveric rigidity does not set in until five or six hours after death. The fair actress naïvely inquired whether it would not be a very severe strain on the patience of the audience to oblige it to wait for six hours until she became stiff after the fashion of nature.

—The following occurred in a chemist's shop in the neighborhood of Liverpool. The wife of one of the merchant princes of that city entered and said: "Oh, Mr. R., are not Epsom salts sold at 2 oz. for 1½d.?" On receiving a reply in the affirmative, madame continued with a sweet smile, "Oh! then I am entitled to an ounce for a halfpenny, as my daughter got an ounce yesterday, and paid a penny for it." And she placed one halfpenny sterling on the counter, as she took a seat and spread her silk robe around.

QUERIES AND REPLIES.

Lanolin as a Vehicle for Cocaine.

Eds. Med. and Surg. Reporter—

Have any trials been reported of the use of lanolin as a vehicle for cocaine, and with what success?

Cotton Gin, Texas. H. W. Moore, M. D.

Pallas Syringe." The most useful Instrument for Vaginal Medication and Irrigation.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

105-15556

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease-producing matter. INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,

36 Platt St., New York.

BURN-BRAE

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful HOME.

Lecture.

TYPHOID FEVER.*

BY PROF. WILLIAM H. DRAPER, M. D.,

Of New York.

The next patient, J. O., is single, 24 years of age, was born in Ireland, and is a laborer. He does not use alcohol to excess, has never had syphilis, gonorrhœa, rheumatism, or malaria. Five weeks ago he became troubled with headache, loss of appetite, nausea, and vomiting, which lasted for two days; but since then he has felt pretty well, though not entirely so. He was treated by a physician at that time, and his symptoms subsided. He has had no cough or sore throat, and no diarrhœa until his present attack began. But six days ago he was suddenly taken quite ill with a profuse diarrhœa, and for two days he had twenty passages a day, which were dark and fluid in character, but contained no blood. Five days ago he suffered from nausea and vomiting, headache, epistaxis, and a chill followed by fever. His urine was diminished in quantity and high colored, and he had a little cough, but with only a slight expectoration. Two days ago he was brought to the hospital, and he was then in a weak condition; he had swollen ankles, a flushed and livid face, and he complained of pain only in the forehead, with great thirst, and a dry mouth and tongue. On his admission, November 29th, his temperature was 103.8°, and his pulse 102, and his respirations 44 per minute. He says he has recently been living on Madison Avenue.

* Abstract of Clinical Lecture.

Gentlemen, you have heard this man's history, and you will observe that he has been ill to some extent for five weeks, but you must note that up to four days before he came into the hospital, his symptoms were not severe enough to keep him in the house or to prevent his working. But then he suddenly had the symptoms which indicate the invasion of a violent fever, namely, chilliness, headache, nausea, vomiting, diarrhœa, and an elevated temperature. We need not, therefore, take any special notice of the symptoms which originated five weeks ago, for they have no special connection with this attack. But we will begin with the symptoms which started six days ago. These were the ordinary symptoms of fever, and they lasted up to the time of his admission on November 29th, at one o'clock in the afternoon. At that time his temperature was 104°, pulse 102, and respirations 44. In taking the vital signs of a patient when first brought to the hospital, you must always make some allowance for the variations caused by the disturbance and excitement of moving. So it was found in this case that after the lapse of four hours there was a slight fall in the temperature. But that night it went up again to 104.5°, and it kept high throughout the whole day on the 30th, and at one o'clock this morning it stood at 104.8°, and now at 3 p. m. it is 104.1°. So you see that he has had a very high temperature ever since he came in. It has not gone below 103.7°, and much of the time it has been 104.8°, which is a very high grade.

When he was first brought in, the doctor on duty sought for the cause of this high temperature. He made a careful examination of the chest and abdomen, and then

took into consideration all the subjective symptoms. But he found no evidences of pneumonia, bronchitis, or pleurisy, nor of peritonitis or any visceral lesion, to account for it. So he concluded that he had to deal with what is called an essential fever, that is, a fever which is not secondary to any local lesion. This is the diagnosis which has been carefully made by a process of exclusion, and this is the plan that is often followed in making a diagnosis. The same mental process is gone through with as in making a diagnosis of an external disease of the integument. But here you take the symptoms of fever to start off with, and you seek for the possible causes; and at last, by excluding the various inflammatory diseases, you are brought down to the diagnosis of an essential fever, as the cause of the symptoms. The essential fevers include the eruptive fevers, and typhoid and typhus fever. But you could here exclude all the eruptive fevers at once, because at the time of his admission he had already passed the period of invasion which precedes the eruption in these diseases, and yet the characteristic lesion of small-pox, scarlet fever, and measles, was not to be found. It remains therefore to make the diagnosis between typhus and typhoid fever. The invasion was more like that of typhus, for it was sudden, and attended by chilliness, headache, a flushed face, and digestive disturbances, such as nausea, vomiting, and diarrhœa. A diarrhœa coming on within the first three or four days is rather earlier than is common in typhoid fever. But you could not say certainly that it was typhus from the character of the invasion alone, for typhoid also begins suddenly sometimes. But now the element of the eruption would help you in the diagnosis between these two; for an eruption first makes its appearance on the body of the patient on the seventh or eighth day in typhoid fever, and on the fourth or fifth day after the invasion in typhus, as a rule. This man came here on the fifth day of the fever, and the doctor now informs me that he then had an eruption of the same character as that which you will now see as soon as I expose the patient's body. It is, you observe, a quite copious erythematous and macular eruption, which involves the limbs, the chest, the abdomen, and the back. These spots are rather dark-colored for typhoid, and they do not entirely disappear under firm pressure with the finger, yet they are not so well marked as the petechial eruption in typhus usually is. The typhus eruption is an exanthematous one, in which there is a deep staining of the skin just over the spots, which, therefore, do not disappear on pressure. Another peculiarity in the eruption which, however, will not yet aid us here, is that in typhus it comes out and remains out as long as the fever lasts, while in typhoid there is a succession of crops, each one disappearing after three or four days, and another then making its appearance. Now, from the fact of the eruption coming out on the fourth or fifth day, and from the characteristics in color and distribution which it presents, I am inclined to look upon this case as one of typhus fever. But I should rather reserve expressing my final opinion, until I see what is to be the course of the eruption. The marked congestion of the face here is also much more suggestive of typhus than typhoid. Besides, in typhoid, during the first week, the fever usually develops gradually, with daily morning remissions and evening exacerbations, and the fever is lighter each evening than at the same hour the preceding day. But in typhus there is usually a sudden invasion and a high degree of temperature from the start, and this has been the character of the fever in this case. If it is typhus fever, by the time you come here again next Thursday, or a day or two later, he should have defervesced. But if it is typhoid there will be a gradual falling off of the temperature, while the fever will still be continuous.

The treatment of such cases consists mainly in the treatment of the fever. This man's surface has been sponged, and he lies naked in bed as you see, partly for convenience in sponging him, and partly because it aids in cooling him. This method of artificial cooling by sponging we now adopt here to the exclusion of the bath, because it saves the patient from the disturbance caused by moving him to and from the bath-room, and we find that frequent spongings are all that is necessary to reduce the temperature and keep the patient comfortable. This matter of reducing the temperature by sponging is important in all fevers, for if you can save the patient only one degree of fever, you are doing him a great deal of service. A too high degree of fever will be followed by rapid emaciation and wasting, while the blood becomes charged with the products of combustion and with effete matters which are poured into it; and this may result in the production of cerebral symptoms which may be attended with serious consequences. This man has not yet developed any cerebro-spinal symptoms. There has been no delirium and no subsultus, and his heart-sounds are still good, and the pulse is not very

rapid, and his general condition is fair with this high temperature. But he may develop delirium, or symptoms of spinal exhaustion at any time, and even before to-morrow morning, perhaps.

There are still other means of reducing the temperature. Diaphoretics and diuretics will do this to some extent; and at the same time you should keep the emunctories open so as to allow the effete matters to be discharged. You should also allow the patient to drink freely of water or other appropriate draughts, in order to cool the blood, and at the same time favor the excretion of effete matters.

It is believed by some that there are certain antipyretic medicines which act on the nerve centres, which are supposed to control the development of animal heat, and so they reduce the temperature. Quinine is thought to be one of these; and indeed, it is in many diseases of a certain class. But in these cases I think it owes its power to its specific effect upon the essential cause of the fever, that is, upon the poison of marsh gas which causes malarial fever. But I very much doubt if it has any effect upon typhus and typhoid fevers, except as a tonic. And the records of this hospital, I believe, bear me out in this statement. In a raging non-malarial fever I do not believe that it has any antipyretic effect. And if it is ever an antipyretic, it is only by reason of some special power over those periodical fevers which are due to marsh miasm.

Alcohol is supposed by some to be an antipyretic of some power in the essential fevers. But I doubt if it is fair to say that it does good by virtue of its antipyretic powers—though no doubt it does do good. But I believe that it does good by furnishing food to the system in a form which it is very easy to appropriate. This man has been taking twelve ounces of whisky every day since he came in, and I think that I shall probably increase the quantity still further, considering his high temperature. I shall not give it to reduce the temperature, but to diminish the risks to which this high temperature subjects him. It will both tend to sustain the heart, and act as a food, and thus supply the force which is so rapidly being destroyed by this great heat—for each degree of heat means so much force destroyed. He cannot convert all this heat into motion, or into the performance of intellectual processes, but it is all going off and being wasted. So he is almost powerless to lift his hand, and his mental faculties are so exhausted that he can scarcely think or speak. Now, you have got to make some provision for this great exhaustion, by feeding the patient. But he cannot digest beef and bread and solid foods, as he could in health, so he has got to have an abundance of an easily-appropriated food. So, in addition to the alcohol, he is taking milk and the various animal broths, and he disposes of all that is given him. The alcohol does not intoxicate him, for no odor of it can be perceived in his breath, but it is all being consumed as food.

Communications.

CONVENTIONALISM IN MEDICINE.

BY W. M. HEPBURN, M. D.,
Of Freehold, N. J.

Conventionalism, in art, we are told, is that which is in accordance, not with the absolute principles of beauty in form and color, but with the opinion and sentiments with reference to form and color which chance to prevail at a particular time, in a particular country, or social class.

The practice of medicine gives, we think, a peculiarly favorable opportunity for the spread of conventionalism, for many reasons, among others these: Professional life is attractive to the present generation, medical colleges are numerous, and diplomas very easily procured, all of which tend to crowd the profession, and thus conduce to increase the number of those who lean entirely upon the opinions formed by others. If these opinions are good, to a certain extent the "leaning" on them is proper, yet it tends to produce a class of practitioners who are governed in their treatment "not by absolute principles thoroughly tested and cautiously received, but by the opinions and sentiments which chance to prevail at that particular time."

Again, we have no specifics. If we had a certain drug which could be relied on to cure a particular disease, and if every disease had a "specific," then the great essential would be to be able to diagnose the disease—the treatment would be a simple matter. We would have absolute knowledge on which to rest. But what are the facts? A glance at the journals or perusal of our current medical works will soon display them. Each writer seems to be convinced that at last the "best medicine" (specific is usually left for quacks), has been discovered. This being the case, the young M. D. just facing

the world fails to remember all he hears and reads; and, unless he be a man of positive opinions, having confidence in self, together with capacity to judge of drugs and practice to test them, he must inevitably take some one or few leading lights as his guide or guides, and is apt to find himself in accordance with "opinions and sentiments which prevail at this particular time," in his exclusive circle, and which may or may not be founded on "absolute principles."

It is not our intention to attempt to assert what are the absolute principles which do, or ought to, govern us in our practice, but simply to state a few of the "conventionalisms" of our day, and our opinion as to whether they are in accordance with the principles which should control us. And first we would speak of hypodermic medication, and especially of the hypodermic use of morphia.

I read, a short time since, in *Puck*, that a physician had cured his patient of alcohol habit by morphine, and broken up the morphine habit with cocaine, and was now looking around for something to give him to cure him of his appetite for the last-named drug. Unfortunately there is enough truth in the picture *to us* to make it appear anything but a joke.

But lately I was told by an aged physician of a man at a summer resort rousing him early in the morning to give him a hypodermic of morphia. The man was half crazy for it, full of hypodermic pricks, and disgusted with the physician's charge because—as the patient said—he had been given injections, by a doctor, for ten cents each. Would it not be well to open morphine saloons, and license men to sell morphine drinks, rather than to have our profession stained by tolerating such physicians?

A patient sends for us. On arriving at the house we find him in great pain. Shall we say, morphine relieves pain, therefore I will give it? Such an opinion arrived at by such an argument, is because the physician is cramped in his resources, or very devoid of professional responsibility. Any tyro could, by such conclusion, from such premises, practice, and practice ably. What then? Shall we refuse to use an anodyne? That depends on whether or not it would be the "proper" treatment, and if it be, it will be because it is founded on absolute principles, whether or not it be in accordance with the sentiments of this particular time.

But let us take a still more aggravated case. Suppose we are called to a patient who has, or thinks he has, suffered for months with pain, and has been "fed" on morphine. He is a good patient, one we wish to please; excellent pay, and in most ways desirable. He knows, or thinks he does, what he needs, and expects to get it. What are we to do with him? The morphine should be stopped (unless dying with cancer, or some other incurable and fatal disease). But to stop it means for us to probably excite his enmity, lose his patronage, or if he consents, his will power being weakened, we will have to struggle for him, take his appetite, study to overcome it, buoy him up, cheer him, and work as if the disease were our own.

That may all be so, but what do we enter the medical profession for? We read of men, in the ardor of the moment, clearing a tube clogged with diphtheritic membrane by applying their lips to the opening, and they are spoken of as martyrs; yet we say a man is an extremist who tells us to take, if necessary, our patients' appetites on us, and struggle with them rather than yield. We can safely say that to one who fully realizes his responsibility not one bill, of a large amount, is on his "books," but that the case has lost him ten times the amount of his account, and some of them could never compensate him by any pecuniary gift. The practice of medicine is of all professions the most responsible, the most to those who are influenced not by conventionalism, except the conventionalism is founded on absolute principles of honor and right. Do we realize that when we gaze at wrecks from the use of narcotics, they are often the results of our "skill." I think we can state it as a fact that comparatively few cases need continuously repeated doses of morphine, except those suffering from incurable and rapidly fatal diseases, and that in cases not necessarily fatal, continuously repeated hypodermics so prostrate the nervous system as to ultimately be the cause of the neuralgia (nerve pain).

Another conventionalism is the repeated changing of drugs during an attack of sickness. I have known a physician, a man of good medical knowledge and large practice, who wrote a new prescription each day and after each visit he made his patient. The sick room soon began to resemble a small drug store. This state of affairs certainly ought not to exist.

It is not, cannot be, a scientific use of drugs. To get proper constitutional effects, in most cases, small, frequently-repeated and *continued* use is necessary. Why then is there a tendency to change drugs each visit, and thus do great injury to the stomach and

no good to the system? Certain conditions, at the present day, tend to produce this evil. One reason is that so many drugs are now put on the market.

Our fathers could carry in small saddle-bags their whole stock, but if one wishes to appreciate how little he knows, let him gaze at the list of "new remedies"—and as to the older drugs, I count two hundred and eighty extracts (fluid and solid). When we come to include tinctures, elixirs, decoctions, aquæ and numerous other preparations and drugs, we get a faint conception of the materia medica and pharmacy which confronts a beginner.

What makes it doubly harassing is the fact that leading firms now advertise their proprietary preparations, and quote such eminent authorities as to their efficiency, that we must be lost to all sense of the glorious advantages open to rising men, unless we test these remarkable combinations.

Let us do them justice. I believe, once in a while, the advice is given to only use the drug by prescription of the physician, as it is too powerful to be otherwise taken, thus allowing the doctor to timidly give his opinion. We object to druggists prescribing, yet is it or is it not a bid for this practice, when combinations are made in which the virtues of the drugs, their use and dose, are given in full? These proprietary medicines may be composed of drugs of the purest kind, and yet to some of them at least, strong objections, of a practical nature, may be brought. Let us cite chloral as an example. If we can believe such an authority as Dr. Ward, Supt. of the Trenton State Insane Asylum, we must accept the following as true: "We still continue to employ chloral hydrate (when not contra-indicated), as our principal hypnotic, and, after using it for several years in the institution, we see no reason for discontinuing it; it is more prompt and certain in its action than most other hypnotics, and in *not a single case* have we ever *known of any untoward result* following its proper administration. The *drug should always* be kept *free from exposure to light and air*, and *always given freshly dissolved.* That it does undergo change when these precautions are not taken, and does not answer the indications for which given, we have had abundant proof. In this state it becomes an irritant, and is frequently followed by vertigo, nausea and other unpleasant symptoms."

We see then that chloral hydrate has an entirely different action according as it is or is not freshly dissolved and properly protected before dissolving. Dr. Hurd further states: "It has been our custom to give it in fifteen to twenty-grain doses, dissolved in one or two ounces of *spring water*," (thus sparing the stomach the effort to digest syrups, etc., and not mixing with other drugs—in fact, getting the true action of chloral).

We hear it stated in the business world that "articles made to order are"—other things being equal—"better than ready made." Here is an impressive illustration of its practical value in medicine.

Again, the simpler form a drug can be given in, the more certain we are of getting its proper action. Small amounts at a time and freshly prepared is preferable to using long-kept drugs, and it is a good thing to know the value of drugs of authenticated virtue before enlarging our list of remedies.

Blessings may become a source of danger. Certainly we ought to be very thankful for the excellent way in which medicines are now prepared. Granules which in their size and appearance would please an ardent homœpath, and containing virtues in proportion greater than our former bulky pills. So with gelatine capsules, and all other proper efforts to disguise disagreeable medicines. But is not the desire to give agreeable preparations carried to such an extent as to take out of our list valuable drugs, such as Huxham's Tincture, etc.?

Horrible mixtures usually do far more harm than good, by causing nausea and disgust for everything, food included; but we do protest against the pandering to public taste to such an extent as to justify preparations of such elixirs as those which, though pleasant to taste, yet cannot possibly contain the amount of medical properties which is said to be in them; and in making this assertion I take the expressions of responsible and able druggists. A prominent city druggist was regretting to me the necessity which compelled them to sell so many of the "agreeable to taste remedies," and neglect the not very unpleasant but antiquated preparations containing true medicinal properties.

A conventionalism which we ought to properly appreciate, is the sentiment which now prevails as to the place drugs should occupy in the prevention and cure of disease. A gentleman, about eighty years of age, gave me a short account of the manner in which he was treated for pneumonia when a young man, by a well known practitioner.

The condensed statement is this: Bled every day, once until he fainted, and given calomel till salivated. In such treatment we see the doctor evidently relying on drugs to cure the disease, and nature (as we say)

curing in spite of the doctor. Drugs in that (and all such cases) take the first, last, and every place. They are the one, the only essential; and what agony nature must suffer in attempting to undo or overcome the wrong innocently inflicted!

But what is our attitude to-day as to the place drugs occupy? First of all, the effort is made to prevent the need of drugs by warding off disease. The common belief is that disease and the physician are closely and clearly related to each other. How then can we explain the devotion of great men to the task of finding means to prevent the arrival of our "friend?" How explain the lives of toil, with but little remuneration, which have for their object the finding of means to keep out cholera and yellow fever? how to prevent mortality of small-pox—how, when they have invaded our shores, states, towns, or families, to prevent the spread of the disease? How many lessons have we been giving as to ventilation, cleanliness, pure water, disinfection of clothes, rooms, and dejections, of hands and instruments? As we attempt to enumerate the steps taken, and view the work accomplished, we feel how weak our efforts are.

But not alone in contagious diseases: what advances in the broad grasp of all diseases. How different our relationship to nature. How rapidly we are learning to come as humble assistants, and, as our age is an age of physical deterioration, owing to many causes, what aids are constantly given us to bolster up our rapidly used-up bodies. Who now would be considered as doing his duty in simply giving drugs, and not advising his patient as to the innumerable details of dress, food, exercise, rest, etc. So that although, once in a while, we still have individuals eating heartily mince pie and such included, while just recovering from acute attacks, yet it is not now the exception but the rule for physicians to realize that drugs *in themselves* are of but secondary importance. What use of treating catarrhal troubles, even with our knowledge of modern instruments and preparations, if we say nothing about underwear, rubber shoes in wet weather, etc.

With all honor for the medical work done in past ages by noble men, yet can we not say that the "sentiments and opinions" of the present place drugs in their proper place by making them only *one* of *many* essentials in the prevention and treatment of disease? Has not our profession attained an eminence —not by isolated cases of progressive individuals—but *as a fraternity*, never before known? Is not this recognition of the place drugs should occupy due to the "sentiments and opinions" of our day? And is it not a conventionalism which we are becoming more and more convinced is founded on "absolute principles."

Conclusions.—Avoid as much as possible the use of drugs giving exhilarating and fascinating sensations. They are not often needed; appetites are so easily acquired and so hard to get rid of, that by using them the last state of our patient may be far worse than the first.

A few good drugs thoroughly tested, and their action known, will prove of greater value to us than our constant attempts to prove the virtue of every newly vaunted remedy.

If I have learned one lesson during my professional life, it is to know the drugs I use, and to know why I use them.

Within the last ten days two cases have come under my notice who had suffered intensely, one with pruritus ani, the other with gastralgia and enteralgia. Both of them had been in the hands of deservedly well known specialists in this country, and one of them of English specialists. Both of them went through many kinds of treatment, and both of them were most relieved by very simple and well known drugs—the one by *hot* water applied by a sponge, followed by a mild mercurial ointment, the other by magnesia, rhei and aromatics.

Our third conclusion is to use as palatable preparations as possible, by using (when not contra-indicated), small, frequently-repeated doses, but avoid simply palatable preparations.

In other words, to be able to appreciate any good conventionalism, but not become a conventionalist.

EPITHELIOMA OF THE CERVIX UTERI.*

BY R. M. HALL, M. D., OF BALTIMORE, MD.

My object in bringing this subject before the Society this evening is two-fold—first, to show how it is possible for a practitioner to err in his diagnosis; and, secondly, to show what has been denied by many practitioners in this part of the country. I remember seeing it distinctly stated a year or so ago, in a New England medical journal, that cancer of the uterus has not been known to occur in the negro race. In the southern part of this country, according to statistics of nearly

*A paper read before the Clinical Society of Maryland.

2500 deaths among whites, one in every 121 was from cancer, while among colored people only one, in about 251. Many physicians, no doubt, in this section of the country, may not even have seen a case of cancer of the uterus among the colored people. I have had three cases that have come under my personal observation: one in a bright mulatto woman, age 65, who died from cancer of the cervix. During her illness I called in consultation the late Dr. McKew, who concurred in the diagnosis; another, a woman aged about 60 years, who died from what I diagnosed as cancer of the cervix, taking all the symptoms into consideration; and from the third case I have the pleasure of presenting the specimen to the Society this evening.

But to return to my first proposition, I confess that in the light of subsequent events I erred in my diagnosis of the case. Knowing the rarity of cancer of the uterus among colored people, and taking into consideration the age of the patient, together with all the various symptoms connected with the case, I concluded I had a case of syphilitic ulceration of the cervix and vagina.

The literature of syphilitic affections of the uterus and appendages is very meagre, so far as I have been able to learn. Bumstead and Taylor, in their late work, say syphilitic affections of the ovaries are rarely met with. According to Lanceraux, they present a close analogy to syphilitic affections of the testicle. This author has only met with the diffuse form after it has arrived at the stage of atrophy; the ovaries were of the usual size or smaller than natural, fibrous in their structure, with scattered cicatrices, and destitute of Graafian vesicles, although the patients had not arrived at the usual age for the cessation of the menses. Lanceraux gives a representation of a case furnished by Richet, in which there was circumscribed deposit of gummy material similar to that found in syphilitic orchitis. The symptoms of these affections are said to be a slight dull pain in the region of the ovaries, possibly at the outset some increase in the size of these organs, perceptible on abdominal and vaginal palpation, a loss of sexual passion, and sterility. It is evident that these signs, taken in connection with the history of the case, can only furnish a probability of the nature of the disease, which may be further increased by the success of anti-syphilitic treatment. No instance is known in which the Fallopian tubes have been affected with syphilis. Certain cases in which uterine tumors in syphilitic subjects have yielded to the internal administration of iodide of potash and mercury, render it probable that this organ is not exempt from the late manifestation of syphilis, but nothing definite is known upon the subject, since post-mortem investigation has been wanting.

Thomas says that upon theoretical grounds it might be supposed that the diagnosis of ulcerated cancer would be so simple that few errors would occur in reference to it. This is far from the truth. A skillful diagnostician would indeed generally arrive at a correct conclusion, but I know of no disease of the genital organs of the female, unless it be pelvic peritonitis, which so frequently gives rise to errors of diagnosis with the inexperienced.

Among other diseases he says it may be confounded with syphilitic ulcer, sarcoma, and so on. From these a differentiation should be arrived at by careful study of the progress of the case, by the degree of constitutional implication, and by the results of microscopic examination. A positive conclusion is not always easy. He says, let it be borne in mind too that syphilitic ulcers have been known to eat into the bladder and rectum, and create very much such a state of things in the vagina as carcinoma develops.

On Friday, November 20, 1885, I was called to see Rachel C., colored, age 32. She was the mother of five children, the last one born in July, 1885. Four of the children are still living, and the last was still-born. She stated that in the birth of the last child the head was delivered naturally, but owing to inertia of the uterus, the child was finally delivered by a physician. So far as I could obtain the history of the case, it seems as though her health began to fail her from that confinement, although she was able to be up and about for some time afterwards. After the birth of the child she complained of pain more or less in the lower part of her abdomen and back, with metrorrhagia. On making inquiry of the family, I learned that her husband was and had been suffering from some sort of disease which was offensive, and made him somewhat lame. The patient, when I was called, was pale and very much emaciated—the pulse was weak and about 100—the temperature was normal. She also complained of sore throat, but on examining the throat the pharynx and tonsils were free of ulcerations, neither were they congested. The tongue was sore, red, glazed, and dry. There was no eruption upon any part of the body, and the hair of her head did not fall off. On the right side above Poupart's ligament, there was a glandular enlargement

which was soft and fluctuating. The patient stated that the swelling gave her great pain, and I concluded it was an abscess, plunged my lancet in it, and there exuded only bloody serum. The mons veneris was partially destitute of hair, and at the superior part of the nymphæ there was a small ulcerated surface, larger antero-posteriosly than from side to side. It was not excavated, but even with the surface. On examining her per vaginam I found the vagina nearly filled with a number of granulations springing from its posterior wall; these were soft to the touch, but did not bleed on manipulation. The cervix had sloughed away so far that I was unable to discover the os. She suffered from incontinence of urine, necessitating the daily use of catheter. The vulva was swollen, and a portion of the thighs was excoriated. The discharge from the vagina was not profuse, neither was the smell offensive. As I stated above, believing that I had a case of syphilitic ulceration, I placed her on anti-syphilitic treatment, consisting of the bi-chlorate of mercury and iodide of potash. On Saturday, the 21st, when I saw her again, the tumor I lanced was as large as before, and she said it still gave her pain. I continued the treatment, and painted the tumor with iodoform in a solution of collodion.

On Tuesday, November 24th, I called in consultation Dr. B. B. Browne, who examined her and coincided with me in the diagnosis. The tumor on the right side belng quite soft and fluctuating, the doctor lanced it quite freely, and there gushed from it nothing but bloody serum. He advised the continuance of the above named treatment, also the washing out of vagina with a 1 to 1000 solution of bichloride of mercury. On the next day, the 25th, the tumor had regained its orignal size, and the cut surface had healed. Notwithstanding the treatment the patient went from bad to worse, and the fæces were passed in bed, unless controlled by the use of opium.

On examining her per vaginam, on the 1st of December, I noticed that there was exuding from the vagina fæces, and on passing my finger up the rectum about one inch, it passed directly into the vagina, the ulceration having completely destroyed the recto-vaginal septum.

I concluded there was no further use in trying the remedies I was giving, and hence discontinued them and gave her only tonics.

She, however, continued to decline, and on Saturday, December 12, she died. About 10 a. m. I made a post mortem, taking out only the uterus, which was so firmly adherent to the left side that I had to cut it off. Dr. Keirle was kind enough to examine the specimen for me, and reports as follows:

The cells of the villi (uterine neck) are hyperplastic and heteromorphous; over-production of large round and oval cells causes enlargement and distortion of the villi, in which there are sparse and not very characteristic pearly globes: clumps of cells have invaded the masculature, which is not arranged as a stroma but displaced and destroyed, thus indicating malignancy.

The growth is a carcinoma of surface epithelium (surface-epithelioma) having its homologue in epiblastic epithelioma (cuticular epithelioma), which conflicts with the mesoblastic origin of the uterus, and is at variance with the opinions of Virchow, whose views, however, are in accord with such origination, he admitting a mesoblast carcinoma, and holding the connective tissue corpuscle to be omnigenerative, denies that the muscular tissue had been *invaded*, and asserts that the carcinoma cells therein are antochthonous, and that the villous overgrowth is an innocent result of common irritation—Vid. "Cellular Pathology." Art. Cauliflower Tumors.

N. G. Keirle, M. D.

Medical Societies.

BALTIMORE GYNÆCOLOGICAL AND OBSTETRICAL SOCIETY.

(*Concluded from page* 302.)

Case 5. Mrs. K., 47 years, 1 child 28 years ago, was brought to me on the first of this month for an abdominal swelling and great prostration, dating only five weeks back. I found a well-nourished but cachectic looking woman, whose abdomen was but little distended, but in whom I could detect, on careful bi-manual examination, a flaccid tumor of the size of an adult head, on the right side. Percussion resonant, except on the right side. Considerable diffuse abdominal pain. Diagnosis, apparently growing ovarian cyst; indication, speedy operation, on account of cachexia.

On March 3d, while stooping, sudden abdominal pain and collapse. Temperature 102.2°; pulse small and thready. Operation having already been fixed for March 4th, was not postponed; on the contrary, the indication for speedy operation seemed in-

creased by the recent urgent symptoms. Feel and appearance of abdomen changed since last examination, tumor less distinct and in the centre. On opening the abdomen, gush of evidently ovarian fluid in large quantity; peritoneum highly congested and covered with recent lymph deposits, certainly much older than eighteen hours (date of pain, etc., day before). Tumor proved to be of left ovary, was very friable, and certain loculi contained pus, which escaped into the peritoneal cavity while the mass was being removed; small pedicle. Thorough sponging, but no irrigation of peritoneal cavity; no shock; drainage. Symptoms of peritonitis on second day. Temperature 102.8° (above which point it never rose). Obstinate vomiting in spite of absolute discontinuance of nourishment or medication per oris, and death yesterday morning—that is, on the fourth day. But very little bloody serum escaped through the drainage tube.

I confess that when I decided to speak on this subject before this Society, I hoped and believed that I had every reason to expect this patient to recover. But although sorely disappointed, I feel that I have not been to blame, and that but for the uncontrollable vomiting (which of course was reflex from the peritonitis) the patient might have recovered.

I have not come before this learned Society to offer advice, but merely to bring before it my experience in this particular class of ovariotomies, with the hope of learning some points from the gentlemen present which may aid me in improving my record of recoveries in cases complicated by acute or chronic peritonitis.

Dr. T. A. Ashby remarked that Dr. Mundé had called attention to grave troubles following the rupture of cysts into the abdominal cavity. He would like to ask the doctor if he had had any experience with cases in which the cyst contents had been poured into the peritoneal cavity as the result of accidental rupture of the cyst wall, and still no unfavorable result had followed. Dr. A. thought this was an exceptional way in which nature dealt with certain cases, the cyst wall being accidentally ruptured by some violence, and the cyst contents effused into the peritoneal cavity. Being of an unirritating character, it was absorbed and eliminated. He referred to a case reported by Dr. J. E. Atkinson, of this city (*Maryland Medical Journal*, vol. iv., p. 229). This case was one of a cyst within the abdomen, diagnosed as *probably* ovarian, *possibly* of the broad ligament. The tumor had reached the size of a pregnant uterus at the seventh month, when it ruptured, and its contents were poured into the abdominal cavity. The growth had not returned at the time the case was reported.

Dr. B. B. Browne said that after the rupture of the cyst in Dr. Atkinson's case, there was discharged a large amount of fluid from the bladder, and the question arose whether, from chronic peritonitis, the cyst had become adherent to the wall of the bladder and ruptured directly into that viscus, or the contents had escaped into the abdominal cavity, and had been taken up and passed off by the kidneys. The patient made an uninterrupted recovery.

Dr. W. P. Chunn thought Dr. Mundé deserved great credit for operating upon so unpromising a set of cases, and also for so fully reporting his results. A correct prognosis could only be arrived at after the collection of a much larger number of statistics than we now possessed. It was in just such cases as those reported by Dr. M., that abdominal surgery had made some of its greatest advances. He felt comforted by the doctor's remark, that it was unnecessary to sponge every particle of effused fluid out of the abdominal cavity, as the drainage tube could be depended upon for its ultimate removal. He referred to a case upon which he operated, and in which some of the cyst contents, a thick sticky fluid, even after careful sponging, had to be left in the abdominal cavity. A drainage tube was used with a good result. He thought Dr. Mundé's remarks upon the diagnostic signs were of special value.

Dr. H. P. C. Wilson thought the position taken by Dr. Mundé was the correct one; that if there was the least chance of saving a patient's life, we were in duty bound to give her that chance without considering what our record might be in a given number of operations. He did not consider the cutting into an abdominal cavity involved in general peritonitis as desperate a procedure as had been supposed. As bearing upon the subject, he related the following case: A woman was sent to him by a skilful physician for the removal of a cystic tumor of the ovary. The patient was about thirty-eight years old, the mother of seven children, the youngest two years old. She reported that she had never had a day's sickness in her life, and in this was confirmed by her physician. There was no abdominal tenderness. A careful examination by himself and Dr. R. T. Wilson left no doubt in their minds that the case was one of simple ovarian cyst. Under antiseptic precautions, including the

spray, Dr. R. T. Wilson opened the abdomen, when about one and a half gallons of greenish-yellow fluid escaped. The case proved to be one of general peritonitis, with a circumscribed peritoneal dropsy, the fluid being confined to the lower front part of the abdomen, and the cavity was formed by agglutination of the intestines behind with adhesions of the omentum and layers of lymph. The patient made a good recovery. He would not hesitate to cut for an ovarian tumor because of the presence of acute or chronic peritonitis. He agreed with Dr. M. that the abdominal cavity should not be sponged out more than absolutely necessary, and very gently.

With regard to washing out the abdominal cavity with antiseptics, he would say that, in a case in which he made an exploratory incision, with the view of removing a kidney, he found a fibro-sarcoma of such dimensions and adhesions that the operation was abandoned. It was necessary to use drainage, and two soft rubber tubes were placed by the side of the tumor and the incision closed. Bichloride solution (1–2000) was injected through one tube, and allowed to run out through the other, twice daily for several days, until, the incision being nearly healed, and the water coming away clear, the drainage tubes were removed, and the patient was considered out of danger. On the eleventh day symptoms of tetanus set in, and the patient died on the seventeenth day. Dr. W. said he thought the antiseptic had nothing to do with the patient's death, and that had it not been used she would have died of septicæmia.

In a case which was sent to him as a simple ovarian cyst, and which he considered such, the patient, shortly before the time appointed for operation, upon trying to rise from her bed, felt a sharp pain followed by collapse. Subsequently examination showed that the tumor had disappeared. The patient made a good recovery, and has had no return of her trouble.

Dr. W. E. Moseley would consider it wiser in all cases, where the cyst contents found their way into the peritoneal cavity, to remove as much as practicable of the fluid. He would not favor violent sponging, as much harm might be done in that way, but he thought a great deal could be accomplished by irrigating the abdominal cavity. He had seen this resorted to by Dr. T. A. Emmet, and did not think any untoward result could be attributed to its influence in any case he had had the opportunity to study. He would not be willing to use a 1–2000 solution bichloride of mercury in this free manner within the peritoneal cavity, as however carefully it was drained out, the large amount of surface would retain a considerable amount of the fluid, and he would fear poisonous effects. He thought that water, freshly boiled in covered vessels and used directly from them, and at the body temperature would be thoroughly aseptic, and would be as effective in every way, and devoid of the irritating properties of the bichloride solution. He did not feel that his experience warranted him in speaking with any great degree of positiveness, but his predilection, in cases of colloid or purulent material, would be in favor of careful irrigation as described, with the use of the drainage tube, if necessary, as an adjunct.

Dr. P. F. Mundé, in closing the discussion, said he was satisfied that in many cases cysts ruptured into the abdominal cavity and their contents were absorbed without any peritonitis resulting. In one case reported by Dr. T. G. Thomas, rupture had taken place several times, temporarily delaying operation. In one of Dr. M.'s own cases, a small tumor, the cyst had ruptured and had never filled again. He had also ruptured a small cyst intentionally without bad results. Dr. Noeggerath had reported that he had ruptured small ovarian cysts in several instances with good results, as had also Dr. Polk, of New York.

As to just what character of fluid was irritating to the peritoneal surface, we had no positive knowledge, but probably the most irritating was the thick, tenacious, so-called colloid material. He did not wish to convey the impression that he disapproved of carefully sponging the abdominal cavity, except in cases where there was present a thick colloid material which would require an excessive amount of manipulation, and even a decided scraping for its removal.

He thought Dr. Moseley's remarks were very pertinent. The case in which he had irrigated the abdominal cavity with sol. bichloride mercury 1–2000 was operated upon some three years ago, when our knowledge of the deleterious effects of this antiseptic was much less perfect than at present. Of late he has always spoken against the use of the solution stronger than 1–5000 or 1–10,000 in irrigating any large cavity. He thought the warm freshly-boiled water was much safer than the bichloride solution, and equally effective in washing out the peritoneal cavity. He considered that the cases reported by Runge, Lusk, and others, and referred to in his paper, demonstrated the fact that in those cases where the cyst contents

were of a thick, tenacious character, the drainage-tube was the proper treatment, and only moderate, careful sponging should be employed.

Dr. F. Chatard, Jr., read the following paper:

Extrusion of Fœtal Membranes at Seventh Month with Subsequent Retraction.

Mrs. B., second pregnancy, up to date of March 7, the thirty-third week, nothing unusual had occurred. On that date I was hurriedly summoned, and obtained from the husband the following data:

Mrs. B. had that afternoon taken a walk of considerable length, and decidedly more than was her custom; as a result, she felt more than usually fatigued, and complained of a sense of weight and fullness about the genitals. Her husband, who was of a rather inquiring turn of mind, made an examination and found a purplish mass protruding from the external genitals. He at once directed her to keep quiet in bed, and sent for me. I saw her about three hours after her walk, and in making an examination found protruding from the labia a soft fluctuating tumor about the size of a small chicken egg. This could be traced by the finger within the vagina, and extended up to and within the external os uteri, which was dilated to about the size of a silver quarter dollar. The tumor was nearly cylindrical in shape, moderately tense, contents perfectly fluid, with walls about the thickness of the membranes at term. There was no apparent uterine contraction at the time of my visit, no pain, and the sensations complained of immediately after the walk had almost entirely disappeared. I directed her to remain quiet in bed, and if labor pains came on to check them with an anodyne mixture of chloral and morphia, as she was still within six weeks of her expected date of confinement. At my visit the next morning I learned the patient had passed a comfortable night, had experienced no pains or uncomfortable feelings, the tumor had retracted so that the lower portion was about half way between the os uteri and external genitals. Directed continued rest in bed. On third day I found the tumor projecting only slightly at the mouth of the womb, which was now contracted to about the size of a three-cent piece. On the fourth day the os returned to its normal size and condition, and no membranes could be felt. The patient completed her term of pregnancy, and was confined on April 11. The labor was normal, the bag of waters forming as usual. The point of interest presented by the case just related is the extreme distension of the bag of waters at this early date, and its subsequent gradual and steady retraction until it returned to its normal situs within the uterine cavity. This, coupled with a corresponding steady contraction of the dilated os and the continuance of the period of gestation, makes a unique case so far as I have been able to investigate the literature of the subject. The distensibility of the membranes has abundant clinical demonstration at term and immediately preceding the rupture of the bag of waters by the efforts of nature, but the retractility is not often made so manifest, though the possibility of such power has been demonstrated by the researches of Baer, Remak, Vulpian, and others. Their investigations have proven the existence of two layers of the amnion, an internal or epithelial layer and an external, composed of connective tissue, more condensed as it approaches the epithelial layer, and of non-striated muscular fibres. It is by the presence of these muscular fibres that we can explain the phenomena which in the present case is demonstrated clinically. At the same time, the history of the case conclusively proves that a marked degree of dilatation of the os, with corresponding protrusion of membranes, by no means necessarily results in immediate or even proximate completion of the uterine effort, if we can by any means arrest further expulsive action. In fact, the presentation of the bag of waters, as here described, may be considered as indicating laxity of the membranes and feebleness of contraction of some duration, a condition offering the best chance of successfully arresting the progress of a threatened premature labor before rupture of the membranes occurs.

Dr. F. E. Chatard, sr., had never met with a case similar to that reported. He had always considered that any considerable protrusion of the membranes made speedy labor inevitable, and he had always acted in accordance with that idea. He now recognized that his reasoning had been wrong, and thought the case of great interest, as showing to what an extent extrusion of the membranes could take place and still the labor go on to full term.

Dr. A. F. Erich said that so far as his experience went, the case reported by Dr. Chatard was unique. He suggested that the membranes were forced out by contractions of the uterus, and the subsequent relaxation of that organ allowed them to retract to their original shape. All cysts have a tendency to assume the spherical form. He thought

this a more plausible explanation than that it was due to contractility of the membranes.

Dr. Mundé, so far as his experience and reading went, considered the case unique. He was inclined to think that Dr. Erich's theory better accounted for the facts than those brought forward by Dr. Chatard.

Dr. Ashby said the case reported by Dr. Chatard must be one of extreme rarity; he had never met with any similar case in his own practice, but he recalled a case which had been recently reported, and which was perhaps more remarkable in some respects than Dr. Chatard's. The case he referred to was reported to the Chicago Gynecological Society, January 13, 1886, by Dr. H. T. Byford. The case occurred in the practice of Dr. C. R. Parke. A discharge of the *liquor amnii* took place, labor pains came on, and the umbilical cord became prolapsed. Dr. Parke replaced the cord and gave ergot. As labor did not progress, he gave morphia and the pains ceased. Three months subsequently, the patient gave birth to a living child. Dr. Ashby said he considered this case unique in character, and, but for the well known reputation of the gentleman who had reported it, he would feel inclined to question the correctness of the observation.

Dr. P. C. Williams thought it very difficult to believe that there could be a rupture of the fœtal membranes sufficiently large to permit a prolapse of the cord, and yet pregnancy go on for any considerable time. Such a rupture must be central, must needs lead to complete draining of the amniotic fluid and be speedily followed by labor. He had often seen cases in which the "waters" would escape during the recumbent position, but would cease so soon as the patient resumed an upright position. In these cases he supposed the rupture was slight and near the *fundus uteri*. Whether the explanation was correct or not, the fact remained that the amniotic fluid might, under certain circumstances, escape in considerable quantities and yet the pregnancy not be arrested.

Dr. H. M. Wilson referred to a case in which there was a pretty constant discharge of the amniotic fluid for two weeks before labor.

Dr. L. E. Neale thought that the presence of muscular fibres in the membranes would sufficiently explain their retractility, and as this explanation was given by such authorities as Tarnier, Chartreuil (1882), and Charpentier (1883), it was worthy of consideration. Although it did not directly pertain to the case reported, he would like to elicit the opinion of the Society upon the more practical question of the treatment of the membranes during labor. Dr. Byford had recently advanced the opinion that the membranes should not always be ruptured after complete dilatation of the os uteri, but that every endeavor should be made to preserve them intact until they protruded at the vulva, with the object that they might also serve to dilate, by water pressure, the vagina, perineum, and vulva. He (Dr. N.) could say nothing in favor of this opinion, either from a theoretical or practical standpoint, but would be pleased to hear from the Society, and especially from Dr. Mundé.

Dr. Mundé did not agree with the teachings advanced by Dr. Byford. He thought that any advantage gained by the dilating effect of the unruptured membranes in the vagina would be more than counterbalanced by the delay in the labor.

Dr. Moseley exhibited "Searby's douche-pan," manufactured by Tirmann, of New York, and sold by Andrews and Thompson, of this city.

Dr. Neale exhibited a modification of Braun's cranioclast (craniotractor, Mundé). The principal modification was in the solid blade of the instrument, which terminated in a *screw-tip* for boring through the fœtal skull, thus combining the perforator and cranioclast in one instrument. Such a modification had been exhibited before one of the European German medical societies and published, he believed, in a number of the *Centralblatt für Gynäkologie*, 1883, and hence was not original. Dr. N. had substituted his entirely removable compression thumb-screw, at the end of the handles, for that of Braun. The instrument was for sale at Mr. Charles Willnis's, of this city.

Dr. W. P. Chunn read the following paper:

A Case of Ovariotomy with Supra-vaginal Amputation of the Uterus.

In perusing the history of the following case, we meet with several points which are interesting. A woman with an enormously distended abdomen not due to ascites is always an object of curiosity to one who has seen something of these cases. In an unusual case, where the diagnosis is gradually narrowed down to a selection between a very large unilocular ovarian cyst and a fibro-cyst of the uterus, the interest taken is still greater; and when, in addition, such a patient has the physical signs and history which would apply to either diagnosis, added to an African descent, we have in hand a case that calls for diagnosis as well as treatment. Such a case was referred to me

through the kindness of my friend Dr. Charles Mitchell, of this city, and the diagnosis and subsequent treatment of this patient is the reason for my presenting these lines to the Society to-night. Upon first seeing the patient I was struck by the very large size of the abdomen, and upon inquiry elicited the following history: She was a mulatto, was rather dark in color, and might consequently be called a negress, although not coal black. She was twenty years of age, the mother of one child 6 years old, had suffered no miscarriages. About three years before I saw her she had noticed that her abdomen was gradually enlarging, symmetrically, from below upwards, until it had attained its greatest size. Her menstrual flow had been regular in regard to time, but slightly exaggerated at some of the periods. She measured fifty inches in circumference around the largest part of the abdomen, and the tumor was prominent and projected the abdominal walls decidedly forward. Palpation showed fluctuation very plainly in all directions. Percussion gave flatness all over the abdomen except high up over the transverse colon and stomach, and to a slight extent in the flanks. Where there was resonance in the flanks, I also discovered fluctuation, showing ascites to be present. Vaginal examination being practiced showed that the tumor did not project into Douglas's pouch, but on the contrary had carried the pelvic floor aloft with it in such a manner that the pouch was obliterated. The vagina was so pulled up in the pelvis that the cervix could not be felt by the examining finger, but the position of the uterus was readily determined by palpation, to be high up on the anterior aspect of the growth, about an inch below the umbilicus. Every motion imparted to the tumor gave a similar impulse to the uterus. Owing to the position of this organ, it was impossible to make use of the uterine sound. Knowing how rare ovarian disease is among the African race, and bearing in mind the physical signs presented, I was inclined to think that I had a case of fibro-cyst of the uterus to deal with. A number of other gentlemen saw the case with me, and, with one exception, confirmed the diagnosis; Prof. Wm. T. Howard, however, thought differently, and pronounced it ovarian, saying that although fibroids were very frequent in the African race, fibro-cysts were as seldom met with as ovarian cysts, and moreover as he had never heard of a fibro-cyst under 27 years of age, he was opposed to the diagnosis of ovarian disease. The literature on the subject proved scant. Thomas, Emmet, Barnes, Courty, Edis, Tait, and Wells, do not mention having seen ovarian dropsy in the colored race. As the patient was rapidly going down hill, it was evident that if her life was to be saved something would have to be done speedily. Her urine being examined was found to contain albumen and all sorts of tube casts in the utmost profusion. However, I decided to do an exploratory incision at any rate, and afterwards be guided by circumstances, being prepared to do hysterectomy if necessary.

On December 22d, the patient was etherized and the usual incision made in the linea alba. With a few strokes of the knife the peritoneum was opened and a glistening pearl-colored cyst came into view. The appearance of the growth showed its ovarian origin. The patient was then turned on the side and about a quart of ascitic fluid was allowed to drain away. The cyst was then tapped with a large Wells' trocar, and three or four pails full of a dark chocolate-colored fluid withdrawn. As the fluid drained away the sac was pulled through the abdominal incision, the hand having been introduced into its interior to break down smaller cysts. As the sac emerged still further, two large attachments to the omentum had to be separated and tied with silk. Both of the ligatures were returned into the abdomen after being cut short. Steady traction being now made, the lower part of the sac was delivered through the abdominal wound, and with it also came the uterus. This organ, as was diagnosticated before the operation, was found six inches above the pubes, imbedded in the anterior wall of the sac. The left side was covered by the broad ligament, which embraced also the lower part of the cyst on that side. On the right lateral border the uterus was free from attachments, but the posterior aspect was imbedded in the cyst wall in a sort of bas-relief fashion. So then it was seen that the uterus was firmly attached by all of its left side by the fundus, and by its posterior aspect. This appearance led me to decide that it would be impossible for me to separate the uterus from the cyst wall, and so I decided to clamp the cervix and pedicle of the sac as low down as possible, and trust to the extra-peritoneal method of treatment.

With this idea in view, the cyst was pulled through the abdominal wound, and Dr. H. P. C. Wilson kindly adjusted his chain-clamp around the pedicle, while I supported the parts, the chain being so manipulated as to embrace the cervix about the

vaginal junction, together with lower part of the ovarian sac, nearly all of which could be pulled up into the bite of the chain. The left broad ligament was also included, as it encircled the lower segment of the tumor on the left side. Fearing that by some chance the bladder might be included in the clamp, I had a sound passed before the chain was tightened; but the sound in the bladder seemed to show that so far from the bladder being grasped by the clamp, it was really nowhere near it. Everything being now in readiness, the chain was tightened up and the tumor rapidly cut away, along with the uterus about the vaginal junction. The stump was then adjusted in the lower angle of the wound, the upper portion of the cervical canal cut out and cauterized, and the overlapping part of the stump closely trimmed off. As some of the ovarian fluid had unavoidably escaped into the abdomen, a Davidson's syringe was used to thoroughly wash the peritoneum. It was found impossible to get all the fluid out of the peritoneal cavity, so after repeated spongings a drainage tube was put in the wound just above the stump, and the incision sewed up with seven or eight silk sutures. The small number of ligatures used was due to the thickness of the stump, which filled up a good deal of the lower part of the abdominal opening. Persulphate of iron was used to tan the parts projecting above the clamp, and iodoform being plentifully sprinkled over the parts, the usual dressing was applied and the patient put to bed. Time of operation, one hour and thirty-five minutes. Pulse 120, temperature 98½ (December 22).

December 23, the day succeeding the operation, at seven o'clock in the morning, the pulse was 150, temperature 101. In the evening of the same day pulse and temperature were the same as in the morning. At night, however, the pulse beat a hundred and sixty to the minute, with a temperature of 102. The patient seemed bright and fully conscious. On the third day the pulse, under digitalis (30 gtts.), came down to 120, and I began to be more hopeful. There was no nausea at any time, and at six o'clock in the evening flatus was passed by the rectum, giving considerable relief. All the while a great deal of serum was coming away through the drainage-tube, but as this discharge ceased, on the fifth day after the operation it was withdrawn, and the opening closed by a suture, which had been before introduced for that purpose. The pulse and temperature, however, remained rather high (pulse 126, temperature 102½), and on the eighth day fluid was detected in the lower part of the pelvis, and fluctuation finally became evident. The position of the fluid was just in front, above and a little to the right side of the remains of the cervix, and caused the abdomen to project just as if the bladder was distended with urine. As the fluid was evidently just beneath the abdominal walls, and as there was great danger of wounding the bladder or ureters by an incision through the anterior wall of the vagina, I decided, with the assistance of Dr. H. P. C. Wilson, to do a second laparotomy. The patient refused any anæsthetic, and consequently I operated without any. An incision was made in the median line about three inches above the symphysis, and the tissues divided layer by layer until the peritoneum was reached. This membrane being finally divided upon a director, a quick gush of foul serum found vent, and the swelling immediately disappeared. A Davidson's syringe was introduced into the cavity, with a view to wash out the whole lower part of the abdomen, but the water was almost immediately returned, showing that the cavity I had to deal with was a shut sac. A drainage-tube was left in place, and the abscess was washed out three times daily, after which it gave no further trouble. The pulse and temperature at once came down as a result of treatment. About the seventh or eighth day after operation a clear fluid was noticed to wet the bandage, and to be continually dribbling away from the abdominal wound. This secretion had the odor of urine, and careful examination afterwards proved it to be such. On January 1, 1886, the temperature rose, and in the morning the thermometer registered 104⅗, or between that and 105. This temperature kept up for three days off and on. At times by sponging and the hypodermic use of quinia and urea, I could reduce it to 103. On the morning of the 3d of January the temperature stood 104⅗. I then gave ʒss of antipyrin at one dose, and on coming back in the afternoon at 3 o'clock found the temperature had come down to 102. The pulse was full and regular at 110. I had no more trouble with the temperature after this, as 20 or 30 grains of antipyrin would always reduce it to 100 or 101. The pulse would also become stronger and less frequent. This treatment was tried and always with the same result. The high temperature was in part due to a pelvic peritonitis which became developed in Douglas's cul-de-sac later on. As this mass behind the posterior wall of the vagina became soft and œdematous, I resolved, also, to make an

incision into the posterior vaginal wall. The patient being lifted on a table, and fortified with a good drink of whisky, was placed on her back, and in this position I stuck a sharp-pointed bistoury into the swelling, and was rewarded by a slight quantity of serum. The swelling, however, did not materially disappear, as much of it was due to inflammatory infiltration in the cellular tissues. This inflammatory attack kept the temperature and pulse somewhat elevated, and affairs progressed as in any ordinary case of pelvic peritonitis.

On the 5th of February a small pelvic abscess burst into the abdominal wound, and afterward convalescence rapidly ensued. The patient went on then to an entire recovery, and is now perfectly well. The clamp came away on the thirteenth day after operation, but the stump had to be trimmed frequently afterwards, and great care was necessary to keep the part aseptic. The pedicle in the beginning was hard and leathery, but as pus welled up around it from the healing of the wound it became quite offensive. Among the questions that might be asked as bearing on the case is the query: What became of the other ovary? To this question, I am free to confess I do not know, as I neither saw nor felt it during my manipulation about the tumor, nor while I had my hand in the pelvic cavity. Other operators have left an ovary behind with no bad result, and I did not feel at liberty to enlarge the incision, to hunt up an organ which would never be of further use. Since the operation she has passed over three menstrual periods, with no disturbance of any kind, and without any flow of blood from any organ, and I see no reason why this condition of things may not continue. The discharge of urine from the wound about the fifth day inclined me to believe that I had included one of the ureters in the clamp, as I have already stated, but I was led to change my mind by the following facts: If the ureter had been included, what would have become of the urine that should have been excreted from that ureter during five days? And again, later on, when the patient began to get about, owing to the upright position, not near as much urine drained away, as did while lying down; and, moreover, when she was up, and emptied her bladder frequently, still less discharge was noticed than ever before. I believe Prof. Simon, of Germany, had a case somewhat similar, where the ureter was tied, and afterwards gave rise to an urinary fistula. He did a second operation, and cured his patient by taking out the corresponding kidney. If only the bladder is constricted, it seems to me that it would prove comparatively easy to open the abdomen and separate the bladder from the adhesion to the cicatrix, and thus close the fistula. As in time the stump will settle deeper and deeper in the pelvis, it may come to pass that the attachments between the bladder and the abdominal wall may become so attenuated that the fistula will be obliterated. Another point of interest about brings the history to a conclusion. Before the operation the urine was examined and found to be full of albumen and tube casts in the utmost profusion. I looked upon this condition as merely the results of pressure and malnutrition superinduced by the abdominal tumor, and another examination two months after the operation confirmed the correctness of this view, as the urine was then without albumen or tube casts of any kind, and only showed some oxalate of lime crystals. So far then from regarding casts and albumen in the urine as a contra-indication for operation, I think the operation in large tumors should be looked upon as the only means of relieving that condition. If I mistake not, a certain operator on the continent did a hysterectomy, and for some good reason left one of the ovaries behind. The woman recovered, conceived again, had an abdominal pregnancy, and was delivered by laparotomy. This case caused me to consider the advisability of entirely closing up the cervix by Emmet's operation, and thus preventing possible accident. In closing, if I may be allowed to mention the idea most forcibly impressed upon my mind by this history, I would say that while the extra-peritoneal method of dealing with the stump may be unavoidable at times, it gives rise to grave accidents, which a secure intra-peritoneal method does not engender, and that it will not be the method of the future.

Discussion postponed until next meeting.

Height and Weight.

Dr. Broca, the eminent French anthropologist, is the author of a formula relative to the height and weight of the human body. It is that the body should weigh as many kilogrammes as it measures in centimetres, after deduction of the first metre. Thus a man measuring one metre eighty centimetres should weigh eighty kilos. Should his weight be more or less, he is too stout or too thin. As men grow older they lose their weight, but as a compensation they diminish in height also.

Bright's Disease without Albumen.

We have frequently cautioned our readers that the presence or absence of albumen is not proof of the presence or absence of Bright's disease.

At a recent meeting of the Société Medicale des Hôpitaux, M. Dieulafoy described several cases of Bright's disease without albuminuria. Last November a woman was admitted to the hospital who presented symptoms of gastric ulcer—vomiting, pain, and hæmatemesis; the vomiting increased, and became incoercible. Milk diet was adopted, and cocaine, mixed with morphine, was administered, with negative results. The patient suffered from constant intense headache. The urine was examined daily, but albumen was not detected in it. The temperature was normal, varying from 37° to 36° Cent. (98.6° to 96.8° Fahr.). Subsequently, she was seized with epileptiform convulsions, became comatose, and died. On the day of her death, and the preceding night, the temperature rose to 38° Cent. (100.27° Fahr.). At the necropsy, the stomach was observed to be in a normal condition. There was a limited area of suppurative pneumonia, and mixed nephritis.

A second case was that of a patient who suffered from violent oppression. The dyspnœa was not accompanied by cyanosis. The lips were red and fever was absent, characteristics of dyspnœa in Bright's disease. Three years ago, the patient had suffered from violent attacks of suffocation, accompanied by angina pectoris. She passed urine ten or twelve times in a night, suffered from headache, and presented the phenomenon of "le doigt mort" (the dead finger). Besides these symptoms, when auscultated on her entry, a *bruit de galop* was heard. The patient passed 200 grammes of urine free from albumen. She was put on a milk diet, and the quantity of urine passed every twenty-four hours, in a fortnight's time, increased from 200 grammes to 600, the feeling of oppression disappeared, and a daily examination failed to detect the presence of albumen. The patient was attacked with congestion of both lungs and died. On the day of her death the urine was slightly cloudy. The necropsy showed that there was congestion of both lungs, and indications of former aortitis; the kidneys were normal in size, but the capsules were adherent; two or three small cysts were observed. The cortical tissue was thin and hard. Microscopical examination revealed interstitial nephritis.

In another case described by Dr. Dieulafoy, the patient suffered from attacks of dyspnœa, vomiting, and the sensation of "the dead finger." The urine was examined every day for a month, but no traces of albumen were detected.

In a fourth case, the patient was ususually obese. She frequently suffered from a feeling of oppression, also from attacks of vomiting. The symptom of "the dead finger" was present; in this instance there was also entire absence of albuminuria. The urine was carefully analyzed during eight months; the result was negative. At the end of that period there was œdema of the lower limbs, and albumen appeared in the urine. The patient was seized with epileptiform convulsions, and died in a state of coma. M. Dieulafoy considers that the facts above enumerated prove that Bright's disease can progress, and yet albuminuria may not appear for weeks or months. To this proposition belongs its corollary proved by another series of observations, that chronic albuminuria may exist independently of Bright's disease. M. Dieulafoy cited a case in which the patient passed urine containing albumen, and had done so for more than two years. It would, therefore, appear that the presence of albumen in urine is not a symptom of semeiological importance, as it is supposed to be; and M. Dieulafoy considers that in these numerous cases where chronic nephritis is free from œdema and albuminuria, the diagnosis should depend on a careful clinical examination, and the grouping together of certain characteristic symptoms, such as buzzing in the ears, slight deafness, itching, frequent nocturnal micturition, the sensation of "the dead finger," especially sensibility to cold, a phenomenon localized in the lower part of the thighs, knees, and legs, *bruit de galop*, etc.

M. Dieulafoy injected into the veins of a rabbit, weighing 2 kilogrammes, 70 grammes of urine, passed by a patient suffering from Bright's disease, without albuminuria. The results were negative; but 90 grammes increased the respiration. An injection of 160 grammes of this urine caused death, but not a smaller quantity. Another rabbit, after

having 160 grammes of urine from a patient with Bright's disease, but free from albumen, injected into its veins, was slightly affected, but perfectly recovered; another survived any doses below 285 grammes; that proved fatal, and would cause death in consequence of exaggerated vascular repletion, independently of the toxic properties of urine.

Beautifying the Skin.

The *Southern California Practitioner* tells us that in the work on diseases of the skin edited by Professor von Ziemssen, Dr. Heinreich Auspitz, of Vienna, makes the following observations upon this subject:

1. A healthy integument is not necessarily beautiful. Even if all requirements concerning diet, residence, atmospheric and climatic conditions, etc., are carried out, the complexion is often extremely bad. The general condition of health has no influence upon the beauty of the complexion, though it has upon the health of the skin.

2. Cleanliness is a *sine qua non* of the beauty of the complexion, though it does not play a great part in the health of the skin.

3. Water is serviceable to the skin in only moderate amounts and at moderate temperature. Very cold or warm baths, when used to excess, diminish the elasticity of the skin and its power of resistance to external irritants.

4. Distilled and so-called soft water are more suitable for washing, and less irritating than hard water.

5. The hard soda soaps are usually preferable to the soft potash soaps for toilet purposes. The quality of soaps depends upon the quality of their constituents and the thoroughness of their saponification. Good soaps must not contain free alkali, or any foreign irritating substance. The addition of moderate quantities of perfumes does not materially change the quality.

6. Simple, finely ground powders, such as starch, magnesia, etc., are entirely innocuous, and often act as a useful protection against external irritants.

7. Frequent application of alcohol abstracts the water of the skin, makes it dry and brittle, and impairs its nutrition. This is also true of glycerine. All toilet washes containing alcohol to any considerable extent should be avoided.

8. This is true to a still greater extent of other additions to washes, such as corrosive sublimate, mineral acids, certain metallic salts, etc.

9. Camphor acts merely as a bleaching powder. This is also true of benzoic resin, sulphur flowers, and substances containing tannic acid.

10. The use of sweet-smelling oils and fats should be employed to a greater extent than is now done for toilet purposes.

11. This is particularly true with regard to the growth of the hair. The nutrition of the scalp should be increased by the rational application of fat (for example in the form of oil baths by means of the application at night of a sponge soaked in oil upon the scalp), and the greater use of simple pomades. These should be applied to the roots of the hair rather than the shafts.

12. Substances should be avoided, or sparingly used, which abstract water from the skin and the roots of the hair.

Case of Simultaneous Amputation of the Right Thigh and Disarticulation of the Left Knee for Railway Injury—Recovery.

Mr. R. A. Stirling thus writes in the *Lancet*, July 31:

This case is put on record as an instance of singular tenacity of life under injuries which usually prove rapidly fatal.

John S., aged 19, was admitted at midnight on December 18, 1885. An hour previously, while engaged shunting on the government railways, which are situated a mile from the hospital, he had fallen on the rails, was struck by the buffers of a carriage in motion, and sustained, through the wheels passing over him, a compound comminuted fracture of the lower part of the right thigh and the upper part of the left leg, with extensive laceration of the soft parts. Hemorrhage had been profuse, and on admission he was suffering much from shock, but was sensible and could speak in a whisper.

The patient, a strong-looking, very muscular lad, was given a few whiffs of the A. C. E. mixture, and in this incompletely anæsthetic state the right thigh was amputated in the usual way at the junction of the middle and lower thirds, with skin flaps and circular muscles. During this operation the pulse flagged much, although not more than a few drops of blood were lost. Enemata of peptonized beef-tea and brandy, with hypodermic injections of ether, were given. While an assistant was dressing the stump, disarticulation at the left knee-joint was performed, the injury being confined to the leg, and the soft parts, though in a doubtful state as regards bruising, still warranting the hope of vitality. Mr. Pollock's method by the long anterior flap was most suitable. The patella

and cartilages were retained. The second procedure added little to the shock, and little blood was lost. All the large vessels were tied with kangaroo tendon prepared after Mr. Girdlestone's plan. Antiseptic precautions and dressings were used for the first but not for the second operation, as to save time I dressed the knee-stump with carbolic oil and opium dressing. In an hour and five minutes from admission the patient was in bed in the ward.

At 10 a. m. the next morning his temperature was normal and pulse 120. He suffered from persistent vomiting for several days, retaining nothing but a little thick gruel, and being fed by enemata. The progress towards convalescence was retarded by the buffer injuries of the left side, including fracture of the sixth and seventh ribs and emphysema. There was no tendency of any of the flaps to slough, and the left stump healed quicker than the right. He was discharged on February 15, 1886, with soundly healed stumps, and when last seen was growing very stout.

Statistical Researches in Connection with the Ocular Manifestations of Syphilis.

Badal (*Archives d' Ophthalmologie*, April, 1886,) has met with 631 cases of ocular syphilis amongst 20,000 eye patients in Paris and Bordeaux. In a number of cases the manifestations were not confined to one region of the eye, but the following table gives the number of cases met with in each region, and shows the relative frequency with which they are attacked:

Iris and ciliary body	242	cases.
Choroid	141	"
Optic nerve	139	"
Third nerve	107	"
Retina	57	"
Sixth nerve	28	"
Centres of vision	25	"
Lens	16	"
Cornea	12	"
Lids and conjunctiva	11	"
Bones of orbit	5	"
Fourth, fifth, and seventh nerves	9	"
Lachrymal passages	1	"

Of the cases of iritis only five per cent. were gummatous. Nearly one-half of all the cases of specific iritis occurred within the first year of inoculation, one of the remaining quarters during the second year, and the other spread over the next thirty years after. Badal, therefore, considers that syphilitic iritis is not, as many maintain, a manifestation of the disease intermediate in time between secondaries and tertiaries, but is most frequently one of the early secondary symptoms. In a third of his cases of syphilitic iritis there were other complications, most of the later cases being accompanied by choroiditis. Of the cases of choroiditis, more than one-half occurred in the first five years after the disease was contracted, one remaining quarter during the next five years, and the rest in the twenty years following. Two-thirds of the cases of specific choroiditis were complicated by other lesions—iritis, optic neuritis, paralysis of ocular muscles, etc.

Operation for Non-Union of Fracture of Tibia.

Dr. J. M. Lewis thus writes in *Daniel's Texas Medical Journal:*

Mr. N. Moody, farmer, aged about sixty, weight about one hundred and seventy pounds, in good health, was thrown from a wagon and his left leg fractured about six inches below the knee (both bones broken).

From the use of badly-adjusted splints, the bones failed to unite. Mr. Moody was not able to bear any weight on his leg, and walked by the aid of crutches. The leg could be moved in any direction, and did not cause much pain; the union was ligamentous. This was his condition when I first saw him, about two years after the accident.

I explained to him that the only relief was in an operation. With the assistance of Dr. J. H. McCain, who administered chloroform, I made one straight incision about three inches long, over the false joint, and crossed it with one of about the same length; dissecting the flaps back, exposing the place of fracture with a small saw, removed the ligamentous tissue, and at the same time *freshening* both ends of the bone (*i. e.* tibia, for I did not operate on the fibula).

After removing all spiculæ of bone, the edges of the wound were brought together with adhesive plaster, and a small point left open for drainage (if any).

The leg was then wrapped in cotton batting, and over this a plaster-of-Paris bandage applied; the leg was elevated and a small opening made in the plaster over the wound to allow drainage; and over this cloths wet in solution of carbolic acid.

The wound healed nicely, and no discharge. The plaster-of-Paris was kept on for about five weeks, when the bandage was removed; union (bony) had taken place, and in a short time he could bear his weight on same, and in three months was walking without the aid of crutch or stick. He is a farmer, and does heavy work on the farm. The operation was a complete success.

The Diagnosis of Tetany.

Dr. Henry M. Lyman thus concludes a paper in *The Neurological Review* for July:

The principal diseases with which tetany may be confounded are:

a. Tetanus.

b. Organic diseases of the brain and spinal cord attended with contracture.

c. Epilepsy.

d. Professional cramps and Thomsen's disease.

e. Spasmodic phenomena of ergotism.

From tetanus it may be distinguished by the absence of trismus, by the advance of the spasm from the extremities toward the trunk, and by the non-occurrence of traumatism. Careful comparison of the course of the disease with the well-recognized phenomena of organic nervous diseases will suffice for their exclusion. In like manner, the uniform preservation of consciousness during the paroxysms, the mode of their development, the usually tonic character of the spasms, the invasion of the limbs by preference, rather than the trunk, the appearance of opisthotonos when the trunk is attacked, and the results of treatment, will discriminate against epilepsy. Professional cramps, or Thomsen's disease, may be recognized by their seat and by their history, as also by their well-marked features. Ergotism is rather rare, and will be usually identified by its association with the faulty diet that gives it origin.

The treatment of the disease must be directed in a general way against the fundamental instability of the individual constitution. The mild form of attack requires no special mode of therapy; but the severe attacks often demand the energetic use of narcotics and anæsthetics for their relief.

Dislocation of Astragalus.

To the St. Louis Medico-Chirurgical Society, Dr. Prewitt presented a patient, a man, who, in October last, fell from a scaffold forty feet, lighting upon his feet and injuring both his ankles. He came under Dr. Prewitt's observation recently. It was difficult to say what the character of the injury was. Both ankles were very much injured, and the patient stated that the physician who saw the case soon after it occurred, thought that there was no fracture, but there was already a great deal of swelling, and of course he was liable to error in diagnosis. Dr. Prewitt was inclined to think there was a fracture of the malleolus in one foot; the other he didn't feel so sure about. There was a projection backwards that was difficult to understand, unless there was a displacement of the astragalus. There certainly had been either a fracture or a partial dislocation, and just which it was now difficult to say. In the ordinary condition of things, the tendo Achillis occupies a position some distance behind the bones of the leg; there is always a space through which one can easily thrust two fingers. In this case that space is occupied in both feet by bone, and what bone it is, is the question. Dislocation of the astragalus backwards is such a rare accident that it is of more than usual interest when we hear of it, and, of course, the reporter of a case of this kind should be very confident of the diagnosis before reporting it as such. He had reported a case of that kind something like a year ago, and presented the patient. In that case there was a peculiar deformity, viz., that peculiar twisting of the foot which is said to accompany dislocation of the astragalus.

Hydrophobia and Imagination.

Dr. W. H. Forwood thus concludes an article in the *Chicago Med. Jour.:*

1st. Rabies in canine species, though probably liable to epidemic outbreaks, is quite rare, but many other diseases of dogs have been mistaken for it, thus giving rise to numerous spurious cases and much unnecessary alarm.

2d. The bite of a rabid dog does not always, nor even in a majority of cases, infect the animal bitten, just as vaccination does not always "take" in children, although the virus may be good. It may not be introduced into the blood, or may be washed off before it has been absorbed, or possibly the system may be from some unknown cause protected against its effects. Of a given number of animals bitten, all remain well for a longer or shorter period, and then a small proportion sicken and die, and the rest show no ill effects other than those resulting from the slight wounds inflicted, which are more serious than if made by a healthy dog. But once the symptoms of hydrophobia appear, death is inevitable. There is no middle ground. Recovery, so far as any well authenticated instance to the contrary is concerned, is *prima facie* evidence of non-infection and erroneous diagnosis. Prevention by means of washing, cauterization, etc., of the wounds, is the only effectual treatment.

Imagination plays an important rôle in medical pathology, and fear is a serious complication in many cases, and it is to be ex-

pected that among intelligent beings, fully conscious of all the horrible consequences liable to follow the bite of a rabid animal, there should be more or less nervous disturbance and mental agony which in certain persons may lead to serious or even fatal results ; but this will not hold good in the case of babies, idiots, insane persons, or any of the lower animals, quite as liable to hydrophobia as the most imaginative men or women in the full possession of their mental faculties.

Sudden Death from Hemorrhage into Abdominal Cavity during Menstruation.

We read as follows in the *Brit. Med. Jour.:* E. J. Penny was called to R. E. T., aged 27, suddenly taken seriously ill. Arrived within ten minutes, found life extinct with evidence of collapse present. Nine hours previous patient was perfectly well; later complaned of pain in region of stomach, which she attributed to her present menstrual flow. Pain increased, dyspnœa followed, death ensuing. Necropsy, made forty-eight hours after, revealed the following: (Thoracic viscera normal.) Body well nourished, rigor mortis present, surface blanched, external genitals blood-stained. Right abdominal cavity contained large quantity of fluid and semi-coagulated blood. Large clot size of fetal head in right iliac fossa. Clot found to have originated from right ovary. Two ruptured Graafian vesicles were seen, to one of which an ovum was adherent. Surrounding blood vessels distended with clot, one of them being distinctly ruptured, at which site clot was adherent. Left ovary showed signs of recent activity. Uterus normal. Abdominal hemorrhage due to rupture of Graafian follicle, which is admitted by various authors to be rare. Hemorrhage in this case was slow, occupying nine hours, while the amount of blood extravasated was enormous.

Treatment of Chronic Metritis.

Dr. Arnsteen, in the *Revue de Therapeutique Medico-Chirurgicale*, recommends the cauterization of the uterine cavity for the cure of chronic metritis. He says in substance that chronic metritis, as is well known, is always attended with irregular menstruation, the flow being too abundant or too scanty, and particularly during the period of induration the patient may at certain times flow freely and at times not at all. When the menstrual function is again regularly established, it will be found that the uterus has regained its normal state. The efforts of the physician should therefore be directed to the restoration of normal menstruation. This result may be brought about by the active congestion induced by the cauterization—the introduction of the cauterizing instrument causing a contraction of the uterus which induces a rush of arterial blood which displaces the venous blood accumulated in that organ. The breaking down of the eschar during the following days brings about frequent contractions which have the same result. The cauterizations may be made, without the patient being confined to bed, every eight days, afterwards twice a week. Sensitiveness of the uterus, exudations, and inflammation of the neighboring organs, are contra-indications for the operation.

Reflex Nasal Cough.

Dr. E. Creswell Baber, in the *Practitioner*, says:

The conclusions which my observations appear to justify are:

1. Reflex nasal cough is only exceptionally produced by probing the anterior part of the inferior and middle turbinated bodies and the tubercle of the septum.

2. In children it is not very uncommon to find that a slight hacking cough can be produced by irritating the anterior end of the inferior turbinated body.

3. The cough reaction may occur without erection of the inferior turbinated bodies and may be intermittent in character.

4. Reflex nasal cough and the act of sneezing are very closely associated, and probably represent different forms or degrees of the same irritation.

The practical outcome of these considerations is, that in cases of spasmodic cough not otherwise to be accounted for, we should do well to examine carefully the nasal cavities in regard to the reflex irritability of their lining membrane.

Efficient Sedative Cough Mixture.

When Dr. H. C. Wood recommends anything, it is a guarantee of its merit. Hence we take the following from the *Therapeutic Gazette:*

R.	Potassi citratis,	ʒj.
	Succi limonis,	ʒij.
	Syr. ipecac,	℥ss.
	Syr. simplicis, q. s. ad.	ʒvj.

M. Sig.—A tablespoonful from four to six times a day.

When there is much cough or irritability of the bowels, paregoric may be added.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

THE HIGHER EDUCATION OF WOMEN.

This was the subject of the President's address at the recent meeting of the British Medical Association, and, reasoning from physiological data, the author held that it was not to be encouraged. The burden of his address was that women were not intended to be men, but rather the mothers of men, and he argued that higher mental development tended to interfere with the functions of maternity, understanding by this term not only child-bearing, but child-nursing as well. He cited numerous distinguished authorities in proof of his assertion, which was meant to apply not only to women in medicine, but to the higher education of women generally. His address was a very fair, impassioned, and impartial exposition of the question, and, as we have said, was directed to show that women are not intended, physiologically, to rival men in the higher developments of cerebration, and that when the force within them is so diverted from its intended channel, the naturally intended physiological processes of women must suffer in consequence.

In support of the view that women are not intended by nature to compete with men, he cites the fact that "Music, painting, poetry, literature, and cookery, have been as free to women as to men; and yet a Beethoven, a Titian, a Shakespeare, a Bacon, or a Soyer has never yet appeared in their midst; and we may rest assured that the day is far distant when a Hippocrates, a Harvey, a Haller, or a Hunter, will adorn the ranks of the lady doctors."

We have always held, and do still hold, very decided views on this question. While we agree with the author's assertion, that it is not wise, neither is it calculated for the welfare of the human race, that woman should endeavor to occupy the places hitherto filled by men; yet, in a free country, we believe that women should be allowed to do as they choose. Let them practice medicine, law, and theology; let them engage in the various mercantile pursuits if they have a mind; and let them also drive street cars in the cold days of winter, let them work the farm in the broiling days of summer; let them *fight in the field,* as well as vote at the polls and legislate at the capitol; let them earn their bread by the sweat of their brows; in a word, let them join man in all his labors and his pleasures, if they wish so to do. Put no obstacle in their way, though, as we have said before, we do not think it wise for women to have this ambition.

Dr. N. S. Davis, of Chicago, in proposing

a vote of thanks to the speaker, remarked upon the influence of the high intellectual cultivation of American women. He believed that woman was abundantly able to occupy her own sphere. She was specially created for it, and should be satisfied with the exercise of these high and noble functions. When she attempted to go beyond them, she must necessarily be a failure. She could no more compete with man in his sphere than could man in hers.

It would be interesting to have some data in reference to the reproductive functions of women who engage in the practice of medicine, as it bears directly on this subject, and we should be pleased to hear from our readers on this subject.

DR. BILLINGS AND THE INTERNATIONAL CONGRESS.

When we heard that Billings was to deliver the address in Medicine before the British Medical Association, in place of the late lamented Flint, we feared that he might be guilty of the impropriety of using this opportunity to give "a slap" to the present management of the International Congress, with which, it is to be presumed, he is not in hearty sympathy. We are pleased to say that our apprehensions were nearly groundless, for the speaker had nothing derogatory to say. His only insinuation was when he referred to the Southwest as the malarial section of our country, and when he intimated that malaria and science were incompatible. However, very shortly later, he informed his hearers that from this very malarial belt had come such men as Marion Sims, McDowell, Battey, Gross and Campbell. The temptation was great, but, like a true soldier and gentleman, Dr. Billings successfully resisted it, and he is to be congratulated on having made the profession of Great Britain much more familiar with the ways of the profession of the United States than they have hitherto been.

VINEGAR AN ANTISEPTIC.

If we consider how rapidly cucumbers would decompose, were they not kept pickled in vinegar, and if we reflect how long they continue in a good condition when thus preserved, we can only wonder that vinegar has not long since been looked upon as a good disinfectant. Certainly we know that the acid fermentation is due to the presence of bacteria, but we also are acquainted with the fact that some innocuous microbes are of great service in the destruction of pathogenic germs.

Dr. Engelman (*Cbl. f. klin. Med.*, 14, '86), has made a number of experiments with vinegar in diphtheria, and come to the conclusion that it is a powerful antiseptic of almost specific effect in that disease. He employed either common vinegar or the officinal acetum, internally 1:4, as gargle 1:2, and undiluted, as spray 1:2 to 3, if applied with a brush, undiluted. An addition of 3:10 vinegar sufficed utterly to prevent the growth of the micro-orgrnisms. It is a special advantage that the taste is not disagreeable, and that, even when applied undiluted, there is no danger of any cauterizing or intoxicating effect.

CANCER AND LONGEVITY.

The curious fact was developed, in the course of Dr. Billings' address before the British Medical Association, that the prevalence of cancer may be taken as an indication of the healthfulness of a locality. Though, seemingly, an Hibernianism, yet the process of reasoning by which this proposition was elaborated is perfectly logical. Thus, Dr. Billings tells us that cancer causes a higher proportion of mortality in those localities which have the greatest proportion of population living at advanced ages, and, in our country, these localities are the New England States. Therefore he deduces, logically, from this fact, the statement that a large proportion of deaths from cancer indicates, to a certain extent, that the locality in which it occurs is a healthy and long-settled one, since it has probably a relatively large proportion of inhabitants, and especially of females, of an advanced age.

NOTES AND COMMENTS.

Hot Baths in Puerperal Peritonitis.

Try them, for Dr. F. W. Fitzgerald, of Chicago, reports a very severe case wherein baths of a temperature of 150°, wherein the patient was kept one hour at a time, thrice daily, acted most happily. When first put into the bath she was so weak, and the tympanitis so pronounced, he could not keep her head from sinking under the water while the body floated. He had recourse to a heavy log surmounted by a pillow, on which he rested her chin, her being face down, in order to facilitate the escape of gas *per anum*, which took place in about half an hour after

immersion. It was most offensive, and the room had to be disinfected and ventilated to prevent her from vomiting. The gas continued to escape in large quantity during each immersion. The benefit derived from the first bath was so marked that for the first time in three weeks she slept soundly for at least four hours, and on awakening could take some burned brandy. She gradually gained, and on the third day asked for the bed-pan, under the impression that her bowels were about to be moved. On removing the pan he was surprised to find from a pint to a pint and a half of pure laudable pus instead of fæces. The discharge of pus continued for about a week, when it ceased entirely. She made an excellent recovery, no fistula being discoverable.

Crushing the Granulations in Trachoma.

Dr. Kramsztyk, writing in the *Gazeta Lekarski*, advises a method of treating granular lids or trachoma which was proposed by Dr. Wicherkiewicz, and which consists of a forcible crushing of the granulations. The eyelid is everted and held by an assistant, and is then subjected to pressure between the two thumb-nails, the operator moving his thumbs to and fro so as to act on as much of the eyelid as possible. Where the granulations cannot be reached in this way, such as those situated at the canthi and on the plica semilunaris, they are pricked with a needle, and then crushed by means of a pair of forceps or some other suitable instrument. The operation is very painful, and cocaine seems to be of little use. Under chloroform, the whole of the granulations can be crushed at a single sitting. Otherwise the length of time and the number of sittings required to effect a cure depend on the abundance of the granulations and the patient's power of endurance. Where other disease of the conjunctiva exists, it must of course be attended to, and different measures adopted. The after-treatment consists in the prolonged application of cold water dressings to the eye.

Pemphigus of the Conjunctiva.

A case of this rather rare complaint, which Dr. William Dickinson reports in the *St. Louis Courier of Medicine*, was thus treated:

Generous diet and tonic regimen from the first was persistently pursued. Quinine and iron, singly and combined, were administered in full doses, and during the last three months arsenic was added. Local treatment by collyria of ac. boracici, and to the blebs local applications of mild solutions of arg. nit. and ox. hydrarg. flav. (amorph.) Galvanism was also employed through the closed lid, one rheophore being applied to the nucha or held in the hand, and during the last month he applied it directly to the conjunctiva, it having been first rendered insensible by instillations of cocaine. By this agent he hoped to reinforce the vaso-motor factor of the great sympathetic, which had become paretic, and which gave rise to the chronic congestion, the extravasation of serum, and the resulting formation of blebs. Eserine was also at periods instilled. Incipient cataract was present in both eyes.

As a summary, and in conclusion, he is not convinced that any agent employed proved itself curative, though temporary benefit was often manifest.

Memorizing Doses.

Dr. G. A. Wiggins, of Philadelphia (*Med. World*, August, 1886), gives some general rules with their exceptions, which are thoroughly reliable.

1. The dose of all infusions is 1 to 2 ozs., except infusion of digitalis, which is 2 to 4 drs.

2. Dose of all poisonous tinctures is 5 to 20 minims, except tincture of aconite, which is 1 to 5.

3. Dose of all wines is from ½ to 1 fl. dr., except wine of opium, which is 5 to 15 minims.

4. Of all poisonous solid extracts you can give ½ gr., except extract of calabar bean, which is $\frac{1}{16}$ to ¼ gr.

5. Dose of all dilute acids is from 5 to 20 minims, except dilute hydrocyanic acid, which is 2 to 8 minims.

6. Dose of all aquæ is from 1 to 2 ozs., except aqua lauro-cerasus and aqua ammonia, which are 10 to 30 minims.

7. Of all syrups you can give 1 drachm.

8. Dose of all mixtures is from ½ to 1 fl. oz.

9. Dose of all spirits is from ½ to 1 fl. dr.

10. Dose of all essential oils is from 1 to 5 minims.

Croton Oil, in Ringworm of Scalp.

Dr. Windham Cottle writes to the *Pacific Record of Medicine and Pharmacy* that the following case of tinea tondens, which he has selected from among his notes, will serve to elucidate the action of the croton oil and salicylic acid in the treatment of this disease. This was an instance of tinea tondens affecting the scalp. Fungus was present, and none are noted as "well" till fungoid growth was unable to be discovered.

Henry C., aged 7½, was admitted at the hospital for diseases of the skin. The disease was first noticed in November, 1877. Nearly the whole scalp was occupied by well-marked ringworm. He was treated by ordinary methods till October 9, 1878, under the use of which the disease had become limited to one large patch on the vertex. On October 9th, linimentum crotonis was applied to the patch. On November 6th, slight suppuration had resulted. Linimentum crotonis was reapplied. Salicylic acid ointment (twenty grains to one ounce) was applied night and morning. On November 20th, he was improved. On December 18th, no evidence of the disease could be detected. He remained under observation till January 31, 1879.

Occlusion of the Os Uteri as an Impediment to Labor.

What will you do when you encounter such a case? Do, if possible, what Dr. F. E. Waxham (*Chicago Med. Jour.*) did.

In one case he detected a very slight dimple in the centre of the presenting tissues. By keeping the finger upon this slightly thickened tissue, he discovered that it became very much thinner with every pain, while as the pain subsided the tissues assumed a very slightly umbilicated appearance. By firm and continued pressure upon this suspicious spot an opening was at length effected and the os gradually dilated.

In another case the os was patulous only to the extent of admitting the very finest surgeon's probe. After this had been introduced and worked about, a second probe was passed, and by separating them the os was gradually and sufficiently dilated to allow the finger to enter. The os was then rapidly dilated, and labor progressed normally.

Bear these cases in mind, and do not get frightened when you find an occluded os.

Rabies.

"Make haste slowly," is a good maxim. We must not accept all that we hear as gospel truth. We have always been skeptical about Pasteur's inoculation for rabies, not because we doubted that preventive inoculation was a possibility, but because we failed to see how its efficacy could be proven, since no one could positively affirm that those who were inoculated and escaped the disease, would have had the disease if they had not been inoculated. We now learn that a farmer from Roumania, who had been bitten by a mad dog, was placed under Pasteur's treatment in Paris. Notwithstanding, the disease developed in due time and proved fatal. This makes the eighth death from hydrophobia after having been subjected to a pretty fair test by inoculations by Pasteur himself. The Roumanian was reported to have been bitten only thirteen days before coming under treatment by Pasteur. It is true that Pasteur has inoculated some 1,400 persons, and only the small number of eight have had the disease and died. But what an infinitely small proportion of those who are bitten by dogs ever develop any ill effects therefrom. Let us wait a while yet.

Revolver Bullet Lodged in the Brain; Recovery.

At the Society of Surgery of Paris, on May 26th, M. Prengrueber presented a man who had fired a revolver at the middle of his temporal fossa. The ball, seven millimetres in diameter, lodged in the brain. The three days following the accident the surgeon abstained from interference, as the only symptoms were general prostration, with lowering of the temperature. Epileptiform attacks having occurred on the fourth and fifth day, M. Prengrueber exposed the cranial wound and removed several bony spicules, which had penetrated the brain. A stilet having failed to detect the bullet, though passed along its course to a depth of five centimetres, nothing else was done. The epileptiform seizures did not recur, and the patient left the hospital at the expiration of a month without any cerebral complication.

Bromides in Hyperpyrexia.

Dr. W. E. Hacon, of New Zealand, thinks that we may reason from other cases of nervous origin that the cause of the high temperature is due to an affection of the nervous system, and if so, the practical point in watching for this symptom is to be most careful that the nervous system has proper rest from sleep. The best typhoid cases are often the most drowsy. Although he is a firm believer in the use of baths, still he thinks much benefit might be gained from the use of the bromides and other sedatives; he really thinks that bromide of potassium every four hours, in full doses, has a claim upon our notice. Even at the onset of a rise of temperature the drug might be tried, and no case of typhoid or rheumatic fever should be allowed to pass more than two bad nights without a sedative being administered.

Manganese in Menstrual Disorders.

It is a strange commentary on the unscientific aspect of medicine, how some men will laud, while others decry a particular drug in a similar class of ailments. Such diversity of views, we suppose, must be explained by invoking the law of individual idiosyncrasy. Some men will say that manganese is a valuable drug in menstrual disorders, others say it is not. The latest writer of the first class is Dr. Thomas J. Kearney, of New York, who, in the *Med. Record* (August 28th), states that he has derived good results from its use in menstrual irregularity in doses of two grains, night and morning. He, however, emphasizes the caution given by Ringer and Newell, that it must not be used in cases of acute congestion and in general conditions of sthenic reaction, neither would he use it during pregnancy.

Gonorrhœa Communicated by Bathing.

Dr. Aubert, in the *Lyon Medical*, reports a case where a little girl, four years of age, was brought to him with a purulent vulvar discharge accompanied by dysuria. He discovered that the mother was suffering from a similar affection, and that the child had first complained four days after having taken a bath with her mother.

It is also related that at the public baths of Santa Lucia, Florence, fifty-five girls were seized with vulvar discharge, some of whom were also affected with purulent conjunctivitis. The evidence seemed to point to the water having been previously contaminated by some one using the bath.

The author concludes that the same water should never be used for a second person.

Anteversion Extraordinary.

Dr. Aveling (*London Lancet*) relates the following: The patient, a lady thirty-eight years of age, was struck in the left eye by the head of one of her children, in October, 1884. Six weeks later she experienced noises in the ears, tenderness of the nose, and pain at the back of the head when she stooped or had the bowels moved. Speech was also affected—she hesitated and stammered when she spoke. The symptoms grew worse until March, 1885. March 22, she complained of having a constant feeling of weight in the pelvis, and could only pass a small quantity of water at a time, and with great effort. Examination revealed extreme anteversion of the uterus, with a full bladder. The uterus was replaced, and later a cradle pessary adjusted, *when all the head symptoms disappeared.*

Venesection in Puerperal Convulsions.

The venerable heart of our distinguished and respected friend, Dr. Corson, will beat with satisfaction when he learns that Dr. McPheeters reported to the St. Louis Medical Society a case of violent convulsions in a woman at the sixth month of pregnancy. Œdema of the feet and general anasarca led to an examination of the urine, which was found loaded with albumen. There were violent abdominal pains in the hypochrondrium, with great headache and a flushed face. The doctor bled her a full quart, with complete relief to her pain, nor has there since been recurrence of the convulsions, which the doctor considered uremic. He was now addressing remedies to the relief of the kidneys. He believed in venesection in such cases, as well as those which could be more properly called puerperal convulsions.

Hybrid.

Before the St. Louis Medical Society, Dr. Funkhouser exhibited a specimen of an embryo five days old, the result of the union of a rooster and a duck. This was the only fertile specimen of sixteen such eggs hatched in an incubator. The doctor thought his experiment tended to upset prevailing ideas about species, general orders, and classes. All sources of error with regard to the roosters and ducks had been carefully avoided. The duck, if kept with a rooster, will allow his approaches. He regarded it as an extraordinary event, that a member of the order of swimmers being crossed with the order of scratchers, should have produced a living result, thus jumping over not only species, but also further. The duck and the rooster are of the same class, but belong to different orders.

Breast Milk for Consumption.

We fear that for obvious reasons, both moral and physical, this treatment of consumption will never come into general use. Yet it has been tried, for the *Medical Record* tells us that Dr. Caius, some four hundred years ago, when an old man, tried to regain his youth by suckling the breast of a woman. He died of stone—not of old age, at least. A more successful application of this remedy is reported to us by a correspondent, who says that a party who had every indication of the last stages of consumption has regained former health, and attributes it to obtaining his nourishment from suckling a healthy nursing woman.

Hen's Blood in the Treatment of Anæmia and Chlorosis.

An exchange truly says that it is not easy to take seriously the claim of Dr. Francesco Brancaccio, of Naples, that the blood of the domestic fowl is an efficient remedy in pernicious and simple anæmia and chlorosis. Dr. Brancaccio, however, reports in detail eight cases to substantiate his opinion, two of these being of primary anæmia. All were first thoroughly treated with the ordinary remedies—iron, arsenic, quinine, and oxygen—but with no success. Hen's blood was then given in doses ranging from eighty to two hundred grammes daily. Examination with the globulimeter were made to determine the diagnosis and progress of the disorder.

The Ice-Bag.

Dr. Thornton Parker tells us in the *Va. Med. Mo.* that in the German hospitals every bed has its framework for the proper attachment of the ice-cap, which hangs just touching the patient's head, so that he can move without upsetting the cap. In almost every disease where the temperature rises above the normal, the ice-cap, if of proper material and properly applied, is indicated. A nail in the wall or a hook in the ceiling will aid in adjustment. The ice-bag is, no doubt, a good thing, but there is such a misfortune as getting too much of a good thing. Look out for gangrene of the scalp, for instance.

A Neat Method of Performing Heller's Test.

Dr. Thomas K. Morton, of this city, is responsible for the following: Take a very small test-tube, two and one-half inches long and one-third inch in calibre. Fill one-third with nitric acid; fold one or more three to three and one-half inch diameter filter papers twice, thus making a funnel, and insert its point into the mouth of the test-tube, supporting it by the forefinger holding the tube. Then pour into the funnel about a drachm of the suspected urine; it will run through quite clear, and form a sharp-cut white ring at the junction of the two tubes if albumen be present.

Red Ants and Leucorrhœa.

Dr. Gillette recently reported to the New York Obstetrical Society a case of vaginitis, with profuse leucorrhœa, which was due to the entrance of red ants into the vagina. The woman had been in the habit of using a fountain syringe in which, when not in use, the ants were in the habit of taking up their abode. On using the instrument they were poured into the vagina, where they caused irritation by their bites. The *Med. Age* says that microscopists will do well to bear this case in mind when searching for the gonococcus prodigiosus, in cases of vaginal discharge.

Vaginismus.

That there is a cause for every effect is a self-evident proposition, and the following case, which Dr. Dixon reports to the St. Louis Medico-Chirurgical Society, warns us always to look for the cause. It was the case of a young lady, married for about five years, who was troubled with vaginismus. She had been confined twice, and the vaginismus was so excessive that it even hurt her on locomotion. Examination showed a number of carunculæ myrtiformes, the excision of which relieved the trouble. Some of them were an inch long, and from a quarter to three-eighths of an inch thick.

Unalterable Cocaine Solutions.

Solutions of cocaine, as those of morphine, atropine, and some other alkaloids, when made with simple distilled water, rapidly become spoiled through the growth of a fungus. Such impure solutions may cause injury to the tissues when injected, or may excite inflammation of the conjunctiva when employed in ophthalmic practice. In order to obviate this, Dr. George Abbott recommends a solution in camphor water. He has kept solutions of atropine to which camphor (one grain to the ounce) was added, for over a year, and has not seen any microorganisms develop.

Ergot in Uterine Fibroids.

When ergot is given for a long time it is apt, in some, to create nausea and disgust. This, Dr. Charles T. Parkes (*Chicago Med. Jour.*), obviated by combining it with morphia, and he reports four cases that resulted in recovery by expulsion of the growth. The ergot may also cause severe uterine pain, which can be controlled by morphia. The preparation used was the fluid extract; dose, half to one drachm every six hours. Duration of treatment, from six days to six months.

Urinary Fistula Maintained by a Calculus.

Before the Chicago Medical Society (July 6th), Dr. Charles T. Parkes reported a case

of urinary fistula of twelve years' standing, from gunshot wound of thigh. The track of the bullet had been such that the urine could escape through the wound on the thigh. Several unsuccessful attempts had been made to close the fistula. While examining the bladder with a sound, Dr. Parkes discovered a stone. Lithotomy was performed, and now the patient urinates per urethram, and the fistula is closing. The calculus was the size of a pullet's egg, and the nucleus consisted of a piece of bone.

The Cause of Inertia Uteri.

Speaking of post-partum hemorrhage from inertia of the uterus, Dr. Walter Coles very wisely remarks, in the *St. Louis Courier of Medicine*, that the more we study the pathological physiology of such cases, the more apparent does it become that the real causes of *inertia uteri* lie hidden far back in the deeper recesses of the nervous system. They are undoubtedly numerous, varied and sometimes obscure, and these must be intelligently sought after and reached before we can expect to find in every case the true physiological remedy, either in the way of prophylaxis or treatment.

Tin Oleate for the Nails.

Thomas H. Irquhart thus writes to the *Therapeutic Gazette*: "I used the tin oleate some months ago on my finger nails, which commenced to split and break soon after I left the army, the result of scurvy, contracted in the military service. I anointed the nails every day with the oleate, and at night applied it on a narrow flannel bandage. In about two months all the nails were sound and tough. I applied the oleate to the nails of a young lady friend, with like success. It is also a beautiful polish for the nails."

Puerperal Fever.

Dr. Hiram Corson thus writes in the *New York Medical Journal:* Of this I can only say that if it is a disease different from peritonitis, I know nothing of it. It is a disease exceedingly rare in the country. If it is caused by the germs that are so guarded against in cities and especially in hospitals, they are inactive if they exist at all in the country; and therefore the directions so urged by Dr. Elliott, Carl Braun, and others, are not needed with us.

The Treatment of Singultus.

To the numerous plans recommended for the relief of hiccough, Dr. R. B. Willliams adds a new one. It consists simply in giving the patient a good pinch or two of "catarrh snuff" to produce immoderate sneezing. He states he has seen the happiest results from it in hiccough of as much as two days' persistence. A simple "catarrh snuff" for the purpose may be made by mixing one part of powdered veratrum album with about four parts of pulverized liquorice root.

Antiseptic Paper.

Dr. Bedoin, of the military hospital of Vincennes, makes light, cheap, and effective applications for wounds by using instead of gauze, unglazed paper (filtering or cigarette paper) first sterilized in a drying cupboard at 110° C., then rendered antiseptic by immersion in a solution of carbolic or boric acid, sublimate, etc. This can be used in layers or plugs, and is covered with thin sheets of gutta-percha.

Malarial Insanity.

What a title! nomenclature gone mad! What are you talking about?—we can hear our readers say when we tell them that there is such a thing as malarial insanity. Yet Dr. Green recently told the St. Louis Medical Society that he had treated two such cases, pronounced by their friends to be insane, but not recognized as such by himself, with antimalarial remedies. In both, permanent recovery ensued.

Reflex Insanity.

We imagine some of our readers will commence to talk about *editorial* insanity, but we must report what we find reliably stated, and we do so find that when Dr. Green told about his cases of malarial insanity, (See above). Dr. Washington mentioned a case of mild insanity which disappeared when he had successfully performed perineorraphy, for an old laceration. Must we not call this *reflex* insanity?—if not, then what?

Sulphide of Calcium.

Sulphide of calcium has been much recommended, in doses of one-tenth of a grain, frequently repeated, in the treatment of boils, carbuncles, acne, etc., and good results are said to have been obtained. It is best administered in the form of pills made by triturating the sulphide with sugar of milk, adding sufficient glycerine of tragacanth to make a pill-mass. The preparation, however, is very apt to undergo decomposition.

Poison Ivy Eruption.

An excellent remedy is said to be an infusion of the sweet fern (Comptonia asplenifolia). This is rubbed freely all over the affected surface, and left to dry. The slightly yellowish stain left by its application wears off in a few days.

The Treatment of Severe Endocarditis.

Dr. A. Ernest Samson (*Practitioner*) reasons out that in cases of severe endocarditis we should give a due trial to the plan of administering the sulpho-carbolate of sodium, or other suitable antiseptic in sufficient doses.

News and Miscellany.

The American Physican.

Dr. John S. Billings thus describes him in his address before the British Medical Association: "I have spoken to little purpose if I have failed to show you that there is a great deal of human nature in American physicians, and it is a kind of human nature with which you are tolerably familiar. Our ancestors were restless, fighters, freebooters, and from these ancestors we have the common inheritance of energy; of what we call "firmness," and our opponents unreasonable, pig-headed stubbornness; of liking to manage our own affairs, and, at the same time, to exercise a little judicious supervision over those of our neighbors; of hatred of humbug and lying; and in spite of our discontent, of a firm belief that our wives and children, habits and houses, mode of business and of treating disease, are, on the whole, better than those of any other people under the sun. Privately, and between ourselves, we grumble and declare that the country and the profession are going to the dogs—nay, we must do so, or we would not be of true English blood; but there is no need for me to tell you that these are only 'growing pains,' and not symptoms of progressive ataxy."

That Bile.

An "old country doctor" thus writes in the *Southern Med. Record:* "A man hobbled into my office one morning, and after seating himself, said: 'Doctor, I have a *bile* on my leg that pains me very much; please examine it, and tell me what to do for it.' On examination, I found a small furuncle just below the knee; 'O,' said I, 'apply some slippery elm bark to it, and it will soon be ready to open.' He left, and the next day returned, hobbling still worse, saying: "Doctor, I don't think I can possibly stand the slippery elm treatment any longer; I have got worse ever since I applied it.' I asked him to let me see it. On examination, I found he had applied a piece of elm bark, about an inch square, firmly to the part with a bandage. I made a poultice of elm bark and applied it properly, telling him that was what I meant the day before. 'Well,' said he, 'I generally try to follow instructions just as I get them, and I don't want no palaver and big words in mine.' I relate this circumstance merely to impress upon the minds of my junior brethren the importance of being very plain and full in giving instructions to ignorant patients."

Syphilis at Nishni Novgorod.

At a meeting of the syphilis section of the Moscow and St. Petersburg Medical Society, a female practitioner, who had been commissioned by the government to inspect the common women frequenting the great annual fair at Nishni Novgorod last year, communicated the results of her experience. There were two inspection stations open from June 16, to September 3, during which time 2,812 examinations were made of 355 women, of whom 49.3 per cent. were frequenting the fair for the first time, and 27.7 per cent. for the second time. Some were professional prostitutes, and some were servants and peasant women who only practiced prostitution during the time of the fair. Of those examined, 6.2 per cent. had urethritis (*sic*), 1 per cent. soft chancres, 0.2 per cent. hard chancres, 5.1 per cent. syphilitic condylomata, and 0.2 per cent. gummata. The conclusions arrived at were, that the main cause of the spread of syphilis is public and private prostitution, such as that carried on at the fair; and that the examination regulations must be improved.

Measurements of Body Surfaces.

According to some measurements made by P. Putilov, of Omsk, the surface of a man's head is 27 times as large as that of an average fœtus at term, while the trunk and upper and lower limbs have respectively 7.5, 7, and 10.8 times the superficial area in the adult that they have in the infant. The mucous membrane of the respiratory apparatus appears to increase much more than that of the œsophagus; the former measuring 13.5 times as much in the adult as in the infant, while the latter only measures 4.7 times as much. The stomach is 50 times, and the small and

large intestine 18 and 22 times as large. The internal surface of the digestive canal is given as 1,200 square centimetres in the baby, and 18,300 square centimetres in the adult; and the surface of the liver is 199 and 774.5 square centimetres in the two bodies respectively, that of the adult being 3.9 times that of the baby.

The Viennese Doctor who Gives no Medicine.

A correspondent of the *Weekly Medical Review* on his way to Vienna met, at Paris, an Englishman. "You are going to Vienna to study?" said the latter. "Yes." "Well, I want your card, for I am going to America next year and may need a doctor, and I want one who has studied at Vienna." "Why?" "For this reason: The old school give large doses of medicine, homœpaths give small doses, but the Vienna school give none, and that is what suits me." And the correspondent remarks, after he has had a Vienna experience, that the Englishman was about right. Prof. Bamburger gives no aconite, in fact no arterial sedative, digitalis as a heart tonic and diuretic, quinine only occasionally, where a high temperature exists which does not at once yield to cold baths or sponging. His frequent use of calomel reminds one of his father's practice, forty years ago. He often devotes an hour and a half to the delineation of a case, and closes with about five minutes' talk on its therapeutic management.

An Ancient Prescription for Hydrophobia.

We learn from a Chicago paper, that a physician in Illinois recently wrote to the State Controller at Albany, N. Y., for a copy of a prescription for an infallible remedy for hydrophobia, on account of which the State appropriated $1,000 in 1806 to pay to one John M. Crous, who claimed to have discovered the cure. A search for the paper resulted in the finding of the warrant upon which the money had been paid, and upon the back of it was written the receipt of Dr. Crous, dated March 25, 1806. The prescription was not found in the Controller's office, evidently having been stolen. The *Albany Gazette* of March 31, 1806, was found to contain a copy. The remedy was compounded of one ounce of the jaw-bone of a dog, burned and pulverized, the false tongue of a newly-foaled colt, dried and pulverized, and a "scruple of verdigreas," raised on the surface of old copper by laying it in moist earth. Directions for treatment followed, involving, in a certain contingency, a dose of 120 drops of liquid laudanum.

A Psychological Curiosity.

A correspondent of the *Brit. Med. Jour.* relates the case of an old man, nearly an octogenarian, who has been in bed for twenty-seven years, being a harmless monomaniac, having the delusion that his satanic majesty always stood at his door to prevent him from going out, and who suddenly, one morning early in June, took it into his head that the devil was gone, whereupon he got out of bed, and with nothing on but his shirt, walked down to the quay (nearly a quarter of a mile) and jumped over. Having been a good swimmer in his early days, he struck out, and although a boat put off from a vessel, he swam ashore. Nobody knowing him, he was taken to a public house, and a medical man was sent for. He was taken home, where he remained two or three days in bed, all the better for his dip. He has been to church, and is now about to resume his former calling, that of a preacher.

A Useful Plant.

Dr. Brandes, a Hanoverian physician, has recently demonstrated in a German contemporary the valuable properties of the anacharis alsinastrum, a water-plant which has hitherto been considered as an unmitigated nuisance, choking up rivers, and altogether useless. Dr. Brandes has remarked that in the district where he lives, and where malaria and diarrhœa yearly appeared in a sporadic or epidemic form, those diseases have gradually decreased since the anacharis alsinastrum began to infest the neighboring rivers and marshes, and for four years have totally disappeared. He therefore proposes that the plant, which came originally from Canada, should be planted in marshy districts, with the view of checking malaria; and the experiment, in view of the evidence adduced in the article under notice, is certainly deserving of consideration.

The Volta Prize.

Le Progrès Médical (August 7) reports that the French Minister of Education has just fixed the date of competition for the Volta prize. It is of the value of $10,000, and was instituted by a decree dated June 11, 1882, in favor of the author of a discovery which shall render electricity economically useful in one of the following applications: As a source of heat, of light, of

chemical action, of mechanical power, as a means of transmission of despatches, or in the treatment of disease. The competition will remain open to June 30, 1887, and the prize will be awarded the following December. Scientists of all nations may compete. A commission, nominated by the Minister of Education, will be charged with the examination of the discovery specified by each competitor, with a view to determine if it fulfil the required conditions.

The Danger in Specialism.

Before a recent meeting of the Chicago Medical Society, Dr. Alfred S. Houghton read a paper on this subject, in which he said that specialties had greatly increased medical knowledge and skill, and had secured for many much reputation. Hence young practitioners grasp any excuse for becoming specialists. But man is not a machine, but a complicated organism, and disease is complex, one organ sympathizing with another; hence it is necessary to examine every portion of the body and treat all organs affected. Hence there is danger in a specialist limiting his sphere of action and usefulness to an unnecessary degree. Another danger is that specialists are apt to become egotistic, and give rise to utterances which they will afterward regret.

Staffordshire Knot.

Mr. Tait makes the tie to constrict a pedicle in two equal parts, as follows: He employs an awl-like needle, with an eye near the point, and threaded with the ligature, to transfix the pedicle at its middle. As soon as the eye appears on the distal side, the ligature is seized and pulled upon while the needle is withdrawn, and entirely cleared. Now there is a loop on one side of the transfixed pedicle and two free ends on the other. The next step is to pull upon the loop until it is long enough to pass over the tumor or collapsed ovarian cyst; then one of the free ends is passed through the loop, and the two ends pulled upon till the loop is shortened, and made to encircle the halves of the pedicle at the line of transfixion.

Hydrophobia in the Ass.

Recently in Ireland an ass alarmed the neighborhood by his terrific braying and violence. It was surmised that he had been bitten by a mad dog which passed through that district some time before. After a couple of days the unfortunate animal died. A few days later a heifer showed apparent signs of rabies, and succumbed within four days. In a day or two another ass went mad. He became most vicious, and rushing into an outhouse attacked a woman, and bit her in the leg. With much difficulty he was fastened up, and after a short time killed himself. The woman had a miraculous escape. Though the limb is severely bruised, the teeth did not penetrate the clothing.

Bacteria in Sea-Air.

Moureau and Miquel have made microscopic analyses of sea-air at various places, and state, as the result of their observations that when the breezes come from the sea the air is almost free from bacteria. When 100 kilometres out at sea the breezes coming from shore are also almost free from them, thus proving that the sea is an insurmountable barrier to contagion. On vessels making long passages it was noticed that although the compartments were not entirely free from bacteria, they contained about 100 times less than in a Parisian home.

A Definition of Gout.

Dr. Milner Fothergill gives the following succinct account of the pathology of gout (*Medical Record*): "When kidneys first appear in the animal kingdom, the form of urinary secretion is uric acid. Uric acid belongs to animals with a three-chambered heart and a solid urine (reptiles and birds). The mammalia possess a four-chambered heart and fluid urine, the form of urinary secretion being the soluble urea. When the human liver becomes depraved or degraded, it has a tendency to form primitive urinary products. To the question, 'What is gout?' the answer is: 'Gout is hepatic reversion, when primitive urine is formed by a mammalian liver.'"

Evolution in Pathology.

Mr. Sutton, in his article, "Evolution in Pathology," says: Inflammation, as read zoologically, can be likened to a battle. The leucocytes are the defending army, the roads and lines of communication are the blood-vessels. When there is an invasion of bacilli, bacteria, etc., the leucocytes march to the attack, and when the slaughter is very great "the tissues become burdened by the dead bodies of the soldiers in the form of pus." Laudable pus, we presume, represents the dead bodies of officers and others who have distinguished themselves in the conflict.

Venereal Disease Dispensary.

It is stated that an infirmary is to be established in New York City for the free treatment of persons suffering from venereal disease, the object being a practical movement toward the suppression and diminution of these diseases. The names of Drs. T. G. Thomas, A. L. Loomis, and other well-known gentlemen, are mentioned as being among the directors." We take the above from the *St. Louis Courier of Medicine.* We may be unusually thick-headed, but we fail to comprehend how *free* treatment will have any influence in suppressing or diminishing these diseases.

Powdered Beefsteaks as Food.

In the *Annales d'Hygiène Publique et de Médecine Légale*, May, 1886, M. Poincaré states that beefsteak reduced to powder is more nutritious than bread, even when meat-broth is added to the latter, but less so than fresh meat. It is not a strengthening form of food. Dogs thus fed would also require bones. It may even disturb the digestion in the same way as food that is decomposed, and should only be used as a last resource, when a morbid condition renders other forms of food distasteful.

Who is a Family Chemist?

A servant maid, age about twenty-two, not over bright, came into the shop. My wife passed through. The maid turned and said to me, "Who is that?" I said, "My wife." She said, "Oh, you are married?" I replied, "Yes, have been for years." She exclaimed —looking sheepish and blushing deeply— "Why, law, of course, I might a' know'd that, coz how could you be a family chemist if you were not a married man?" She had seen the words "Family Chemist" on the labels.

His Medicine was Invincible.

Family physician meets patron on the street? "Ah, good morning, Mr. Simpson, how is your good wife to-day?" "She's ever so much better, sir—a little restless the fore part of the night, but very quiet afterwards." "Yes, yes, that's encouraging; my new preparation is sweeping all before it; don't you think so, Mr. Simpson?" "I know it, sir. By the by, Dr. Dosem, the funeral is appointed for to-morrow afternoon; may I expect you to be present?"

Photographing in the Dark.

With a lens made of rock salt it may be possible to photograph in the dark. The *Photographic News* states that Abney has succeeded in preparing plates which are sensitive to the rays lying beyond the red end of the spectrum, the dark heat rays, and with such plates used with a rock-salt lens there should be a possibility of photographing bodies which possess a high temperature, although that temperature may be far below that needed to render them self-luminous.

Medico-Legal Laboratories in Spain.

The Spanish Ministry of Justice has arranged for the establishment in Madrid, Barcelona, and Seville, of laboratories of forensic medicine. After the middle of September, analyses which may be ordered by magistrates will be conducted in the new institutions—a provision enabling experts nominated in the interests of accused persons to be present during the performance of such analyses.

Deaf-Mutism in Spain.

According to Señor Don J. Lopez Navalon, principal of the National College for Deaf-mutes in Madrid, the number of persons afflicted with deaf-mutism in Spain is more than 10,000. For these there are, besides the Madrid College, which is supported by the State, only four other institutions in the provinces, and these are all supported and managed by private enterprise.

Poisoned Honey.

At a recent meeting of the Dresden Agricultural Society, a local pharmacist reported that in a neighborhood where the deadly nightshade grew abundantly the bees had incorporated with the honey sufficient poison from these flowers to account for numerous and occasionally fatal cases of poisoning.

Practitioners in Illinois.

The Illinois State Board of Health has passed a resolution that it will not recognize any diploma issued at any college where the number of graduates exceeds forty-five per cent. of the matriculants.

—A solution of menthol, two to ten grains in the ounce, is said to be a very effectual remedy in the treatment of the troublesome itching which accompanies urticaria, eczema, and pruritus.

Items.

—For hiccough, give a pinch of snuff and produce a sneeze.

—A novel professorship is the establishment of a chair of the Chemistry of Food in the University of Berlin. The incumbent will rank as professor extraordinary.

—The London Hospital Sunday Fund amounts this year to over one hundred and eighty thousand dollars, being $25,000 more than it was last year.

—Irish Tramp.—"Is this a lying-in-hospital, mister?"

Janitor.—"Yes, this is a lying-in-hospital."

Tramp.—"Then I guess it's the right place for me, for I've been lying out these three nights."

—An electric sword is said to have been invented in Shanghai which, when the point touches the person attacked, sends a powerful shock through him. The battery, it is said, is carried at the waist of the wearer, and is connected with the sword by means of insulated wires.

—Sandy—"I want a cake of soap, Mr. M'Intosh." Chemist—"I canna let ye hae a cake of soap on the Sawbeth day, Sandy." Sandy—"But ye sell'd that lassie peppermint drops." Chemist—"Ay, ye can sook peppermints in the kirk, *but ye canna wash yersel' there.*"

—The Continent boasts of an important contingent of medical ladies. No fewer than one hundred and seventy women are at this moment inscribed at Paris *en cours d'études*, though some of these have died or have withdrawn. In Switzerland, since 1874, fifty-five women have received the M. D. degree, of whom seven are British.

—The *Journal of the American Medical Association* says that a young man recently entered a dispensary in Chicago, and inquired if that was the house for the diseases of women. When assured that it was, he said: "Well, I've got a disease of a woman, and want to be treated."

—Puffendorf tells the following: "A man who had sore eyes went to a horse-doctor for relief. The doctor applied to his eyes an ointment he was accustomed to use on horses. The man became blind, and sued the doctor, but the judge acquitted the horse-doctor, on the ground that if the man had not been an ass, he would never have applied for relief from a horse-doctor."

—In Holland ladies are gradually usurping the occupations of the pharmaceutical assistants. The periodical State examinations have just been held, and the result is highly favorable to the fair sex, and startling to mankind generally. Out of a total of 55 candidates, 19 out of 31 female candidates, and only 8 out of 24 male candidates, were successful.

—The director of the agronomic establishment of the Nord, of France, communicated, at a late meeting of the Agricultural Society, his experience that nitrate of soda yields a much better result if applied to the soil as a solution than in dry condition; five parts in solution being equal to eight parts of the dry material. The same authority also states that in most cases nitrates are preferable as manures to ammonia salts.

OBITUARY NOTICE.

J. L. Suesserott, M. D.

This well known and respected gentleman died in Chambersburg, Pa., July 16, aged fifty-seven years. He studied medicine with Dr. S. H. Senseny, of Chambersburg, and dentistry with Dr. J. H. McQuillen, of Philadelphia, graduating from Jefferson Medical College in 1851, and subsequently receiving the honorary degree of D. D. S. from the Pennsylvania College of Dental Surgery. Immediately after his graduation, he began the practice of medicine and dentistry in his native place.

In 1858 Dr. Suesserott was chosen professor of the principles of dental surgery and therapeutics in the Pennsylvania College of Dental Surgery, which chair he filled with great acceptance until August, 1862, when the demands of his practice compelled his resignation of the professorship. Dr. Suesserott took a deep and active interest in whatever was calculated to advance either the science or the art of dentistry. He assisted in the organization of the American Dental Association, was prominent in the formation of the Pennsylvania State Dental Society, served as the first president of the Cumberland Valley Dental Society, and was a trustee of the Philadelphia Dental College from the time it was chartered until his death. As an operator Dr. Suesserott was regarded as possessing more than average skill, and as a teacher he labored to prepare those whom he instructed for an intelligent practice of their chosen profession. In later life he was a delegate to the American Medical Association, a member of the Medical Society of the State of Pennsylvania, and of the Franklin County Medical Society. He expired in the same room in which he first opened his eyes to the light of day.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

NOTES ON MEDICO-LEGAL TOPICS.

BY HENRY A. RILEY, ESQ.,
Of New York.

THE SUICIDES' WARD OF BELLEVUE HOSPITAL.

The *New York Tribune* contained, a few days since, an interesting letter from Marcus Rosenfield, an inmate of Bellevue Hospital, where he was taken after attempting to commit a felony at the Germania Bank. He made an effort to escape arrest and jumped from a window fourteen feet from the ground, with such serious results that he had to be taken to the hospital. While there, he had an opportunity to observe the scenes in the suicides' ward, or at least the ward where those who attempted suicide, but failed, were treated. The account of his observations is of great interest, and one would hardly believe that it was written by a person who was a criminal himself. The following extract has none of the dry details of the clinical report, and may be criticised as inaccurate in some details, but there is no doubt that it is well written, and its length will be pardoned:

"Another case of self-inflicted suffering is that of one Miller, a patient in the bed adjacent, who, in a frantic moment, aimed to shoot himself through the head. The bullet, however, glancing around the frontal bone, pierced the optical cavity, and passing out of the right eye, carried that optic with it. The other eye became inflamed and morbid, and in order to save that member, an operation is made daily, by which the orb is lifted from its socket and treated chemically. These two cases, however, are minor incidents compared with the subject that was presented in the case of Hillman, the merchant, who shot himself at the Grand Union Hotel recently. Your readers will remember the case; how, having desperately attempted to kill himself by putting six bullets into his head and body, two of which lodging in the throat would have been sufficient to prove fatal, the man was conveyed to this hospital, trephined, tracheotomized, and otherwise carved, until his life had been actually placed beyond danger! It is this remarkable case and the incidents of the night following the operations, which I witnessed, that prompt the title of this sketch. The patient was received here about 5 p. m. Within fifteen minutes thereafter, under the supervision of W. F. Dalrymple, who occupies the position here of ward-orderly for the facilities it affords him to pursue his medical studies, the man was washed, dressed, and placed in proper form for treatment. At six o'clock Drs. Mitchell, Howell, and Clark began operations. Placing the sufferer under the influence of ether, the surgeons, under the direction of Dr. Mitchell, proceeded with their knives. Has it ever been your lot, reader, to witness an operation where every turn, each movement, each beating of the heart, is watched with bated breath—where the slightest pulsation of an artery, the least variance from an organized purpose, has a significance of life or death?

"For an instant the surgeon wavered; then with a heroic and steady hand he cut a slit into the throat and proceeded to find the ball. Tacheotomy! Imagine the act of cutting a man's throat to save his life! Separating the glands of the trachea, a probe was inserted, and in an almost incredibly

short space of time the bullet was extracted and a tube was placed in the opening of the throat, made by the incision, through which the insensible man could gain and exhale his breath. A ghastly sight! Verily; for I noticed even the attendant turn his head for an instant and gaze into the distance. But there was work to be done, and speedy work at that. One of the balls which had been fired directly downward through the summit of the head had fractured the skull, and a portion of the bone was pressing on the brain. This had produced a partial paralysis over the left portion of the man's body, and it was necessary in consequence to keep hot vessels applied to his nether limbs during the operation. It was also necessary to dislodge this pressure at once, and rid the brain of the hidden bullet, to avert paralysis of the heart. Aware of the necessity, therefore, of a dual operation, howsoever dangerous, the intrepid surgeons ventured upon an immediate action. The man lay already exhausted from the first operation; his breathing was becoming more labored, and more ether had to be administered. Dr. Mitchell saw the necessity of a swift decision. With gentle but firm hand the wound at the top of the brain was laid open, and one by one the fractured portions of the skull removed; the bullet at the base was discovered, loosened from its surroundings, and quickly extracted, after which the scalp was drawn over and sewed up—all within a space of time quicker than pen can describe.

"The surgeon smiled. With silent admiration I gazed for a moment through the blazoned screen upon the features of this clever man of lances. There was a curl of triumph upon his intellectual features; yet as he turned away to clean his reeking instruments, I involuntarily shuddered. That night was a red-letter one in my career. For nine long hours there lay beside me the form of a man balancing in the scales of life and death—a long, thin, frail body, with the aspect of a dead man's stare and repose, a head and face with all save the eyes wrapped, tied, and bandaged into inrecognition, and the grating breathing from a throat through which a cold metal tube served as the only means of life and relief! Here was a phase of human endurance! The effect of the ether had died away, and an hour passed before the man moved. Then he turned his eyes full upon me. I shall never forget that look of woe. 'Neath the flickering gas-jet I saw a scene that will ever be impressed upon my memory with indelible horror. The hands of the suicide, which had been fastened down to prevent self-injury, had broken from their fastenings, and the unfortunate man was frantically clutching at his throat in an attempt to strangle himself by tearing from him the tube through which he breathed! I cried out to the orderly, who came swiftly to the rescue.

"'Why do you want to save my life? I *want* to die! Give me peace—give me peace!' the poor fellow wailed; and as he was gently turned back into the bed, I could feel the sincerity of his cry. 'Twas the language of the suicide—that mystic language which has baffled scientist and the world from time unspoken.

"One of the most curious paradoxes I have ever heard is one told here, that time and a lapse of events will convert a would-be suicide to a love of existence; in other words, that in the majority of cases a serious attempt at self-murder will, if made at the cost of much physical suffering, eventually make the recovery of life a blissful desideratum. Curious though it may seem, a most positive establishment of this theory has just been evinced in the above case. The occurrence of which I write took place on Friday of last week. Since that time the patient has been slowly but steadily convalescing. A reaction, too, mentally—or morally, as you would call it—has taken place; an entire revolution has occurred, so to speak, and the man now actually wants and seeks to live. As I write this the poor fellow is holding out his wan, thin hand to me, and he has muttered a few intelligent words of greeting. The cruel tube has been taken from his throat, the wound sewed together, and liquid nourishment of milk and eggs administered. In a fortnight perhaps he will be again upon his feet, and once more a mortal to go forth and mingle with the living, to endure or to ignore the vicissitudes and trials of life, as may seem most fitting to the caprices of his own imageries. MARCUS ROSENFIELD.

"*Bellevue Hospital, August* 26, 1886."

PHYSICIANS' FEES.

The subject of "fees" is of perennial interest to physicians, and a recent discussion of the subject by a professor of medical jurisprudence in a New York college will be of interest. He says on the subject of large fees: "A physician is, of course, completely at liberty to establish a standard of charges as high as he pleases, and he may make it so high that none but millionaires will be able to employ him. No one can object to this. If, then, he does give professional attention to a person who is unable to pay such fees, and chooses to charge him at a lower rate

than his custom would warrant, this, also, would be a simple act of charity, to which no one could object. But for a doctor deliberately to add to his usual rate of charges an amount based simply upon the supposed ability of his patient to pay, seems to me to be lowering your profession to the level of soulless usurers, and sacrificing all that is high and noble and philanthropic in it to the mere love of lucre. I do not know that the precise question has ever been presented in this country, but I doubt very much whether our courts would sanction any such practice."

LIFE INSURANCE.

The subject of life insurance is an important one in medical jurisprudence, and there has been a recent interesting case in the English Court of Appeal, bringing up some new points. It appeared that a person applied to a company for insurance, and answered in his application a large number of questions as to his habits, health, etc. In addition to this, as is the usual custom, he was examined by a physician, and upon his report the risk was accepted by the company, but only on the terms that there should be no insurance until the premium was paid. The gentleman was prepared to pay the premium whenever the papers were ready, but before they were ready, a change had come in his health, making the risk a poor one, and the company refused to issue the policy. The premium was tendered, but refused by the company, and a suit was brought to compel the issuing of the policy. The court declined to take this action, and held that there was no binding contract until the premium was paid. If it had been tendered at the time of the acceptance of the application, instead of waiting for the preparation of the policy, the company would have been obliged to issue the policy.

CREMATION.

The subject of cremation has attracted the attention of the Pope, though there has been no effort made to introduce the custom into Rome, and a decree has been issued which forbids any dalliance with the new heresy. All faithful Catholics are forbidden to affiliate themselves with any cremation society, and no one is to be permitted to order or facilitate cremation, even when the testator himself has directed this kind of sepulture, and his executors and next of kin are desirous of carrying out his wishes. This decree will have considerable influence in France and Italy, but in this country few Catholics have expressed themselves in favor of the fire burial.

KILLING OF BIRDS.

The Legislature of New York at its recent session passed a strenuous law forbidding the killing of many kinds of birds, mentioning some twenty varieties by name. The law is intended to strike at the prevailing fashion of wearing the wings or whole bodies of birds on bonnets, a custom which is fast destroying all the varieties which have any beauty of plumage.

JUMPING FROM THE BROOKLYN BRIDGE.

A boy named Collins made an attempt a few days ago to jump from the Brooklyn bridge, but the watchful eyes of a policeman discovered him before he had an opportunity to try the dangerous plunge, and he was ignominiously marched off to the police station. The successful attempt made a few weeks since had enabled the diver to make a good bargain with the owner of a dime museum, and the pecuniary profit of this transaction, it was thought, induced Collins to try the same fearful jump. It would probably end the miserable attempts at dropping from the Brooklyn bridge, and the even worse attempts to swim the whirlpool rapids at Niagara, if the authorities could secure the conviction and imprisonment of one or two of these tempters of Providence.

In the Collins case the desire seemed to come almost entirely from the idea that there was "money in it" to the successful swimmer. One of the papers, in giving an account of the examination at the police court, says that Collins was employed in a spice house, and when asked what he did there, replied: "I adulterate the spices." It would seem as if it were hardly worth while to attempt to prolong the life of such a fellow.

CYSTITIS: PATHOLOGY AND TREATMENT.

BY FREDERICK HORNER, M. D.,

Of Marshall, Fauquier Co., Va.

Cystitis or inflammation of the bladder affects perhaps one-tenth of the human family in the colder climates who have attained the age of sixty, either idiopathically or as a consequence of disease of the kidneys, prostate gland, or from calculi in the bladder. It begins by rigors, fever, by great pain in the region of the bladder, attended with a frequent and painful discharge of urine. The pain recurs in paroxysms after each attempt of micturition, and is most felt in the region of the prostate gland and at the mouth of the urethra, extending often to the

loins and involving the perineum and diaphragm, when succeeding frequent attacks of lumbago, rheumatic fever, or gout, with lithic and phosphatic deposits. In its advanced stage, muco-purulent deposits may be detected on the sides of the urinal mingled with the urine. The seasons most favorable for its development are the autumn and spring. It occurs in both sexes, though most frequently in males; even the lower animals, as the horse and cow, are not exempted. Few aged persons of a gouty or rheumatic diathesis escape an attack, especially if the kidneys suffer from nephritis. When the urine has in it on examination albumen and the casts pathognomonic of Bright's disease, the disorder, save as catarrh of the bladder produced by cold or a lesion, or by congestion of the prostate gland, is not a primary disease. In proof that it is rare in warm climates, Dr. Joseph Jones, of New Orleans, mentions that in his practice at the Charity Hospital, 1869–86, he was called upon to treat only six cases of cystitis.

It is important to recognize the disease in the early stage and to distinguish it from disorders with which it may be confounded. If an incipient gonorrhœa, its history will indicate its nature; the pain of nephritis lies more around the umbilicus than in the hypogastrium, and extends along the course of the ureters, while the pain of cystitis is above and behind the pubes, is increased by pressure, is trifling at first, but generally becomes severe, and is attended by a burning sensation extending sometimes to the glans penis, to the loins and abdomen. A *pathognomonic sign* of cystitis is an incessant desire to void urine, which is discharged drop by drop, and with much pain, straining, and heat along the urethra, with a feeling of tension and fullness over the pubes. The patient presents an anxious expression of countenance. When suppuration occurs, the urine has a purulent odor. The physician should never lose sight of the possibility of the existence of a calculus in the bladder, which alone can be detected by the use of the sound, and is sufficient to cause cystitis.

Treatment.—Absolute rest in the recumbent position day and night should be enjoined, with the strictness observed in the management of a case of fracture. The trunk and lower extremities should be elevated on an inclined plane. A firm hair-pillow will answer for the former purpose, and the foot-board or a chair for the latter. The acute stage of cystitis, commencing, as it does, almost invariably with symptoms of inflammation, rigors, and fever, must be treated by low diet. It is best to give purgatives, which, after absorption into the blood, do not irritate the urinary passages. Mercurials will be best retained, and nothing is so good as castor oil, if the stomach will bear it. Sir Benjamin Brodie's gout pill is excellent.

℞. Mass hydrarg.,
Ext. rhei,
Ext. colocynth co., āā ℈j.
Ext. colchi. acetas, gr. xv. M.
Divid. pilulæ, xv.
Three to be given at bedtime.

For the relief of pain and to ensure sleep, soluble hypodermic tablets of morphia, atropiæ sulphas, and soda may be used every three hours. The patient himself, or nurse, if supplied with a hypodermic syringe, can apply this remedy when urgently demanded. Suppositories, aq. ext. opii, gr. j; ext. belladonnæ, gr. ss, may also be recommended. Bromo-caffeine is a most valuable hypnotic; it exerts a calming influence on the cerebral nerve centres, relieving headache, and usually the following morning acts as an aperient. Pilo-spongeine cloth, saturated with hot water or infusion of hops, applied to the entire abdomen, will contribute to the comfort of the patient, and will also relieve the local inflammation in the bladder and adjacent tissues.

It has been remarked that acute cystitis may be one of the sequelæ of gout or an attack of rheumatism, or some disturbance of the general health consequent upon lithiasis. Under these circumstances, either the citrate or acetate of potash, followed by iodide potass., should be prescribed, and all there sources of thermo-theropathy invoked. The thermal mineral waters either of the springs of Virginia or Arkansas will hasten the relief, if not the permanent cure of this class of patients. Dr. Gustavus B. Thornton, President of the Board of Health, Memphis, says: "Drinking these hot waters contributes to cure dyspeptic symptoms; they act as a valuable diuretic, increasing the volume and neutralizing the acrid and irritating products of the urine. The patient is directed to lie full length in a bath tub, the water at about 90°, for eight or ten minutes, and then after rubbing off will go to bed and lie between blankets for an hour. The bath should be taken at 11 o'clock a. m. each day for the period of ten days, unless contra-indicated by depression of the general circulation. When there exists chronic cystitis, Dr. Thornton recommends the use of Key's Fountain Irrigator, an apparatus which is adapted to the male urethra. It consists of a rubber bag with the capacity of a half gallon, and a soft rubber catheter which is

attached to the end of a tube provided with a stop or clip for arresting the flow of water at will.

Of course for the relief if not permanent removal of the gouty rheumatic diathesis, the American medical profession are now a unit in recommending the use of the water of the Buffalo Lithia Springs of Virginia, Spring No. 2. The effect of the Lithia water is to increase the quantity of the urine, changing its chemical constitution, rendering it rapidly neutral if previously acid, and afterwards alkaline. The high color becomes pale, and having deposited copiously it becomes limpid and transparent. As an alkaline diuretic this mineral water is invaluable. Its effect is to dissolve the uric acid, and thereby the symptoms referable to the nervous system and threatened coma and uræmia are relieved. Dr. Hunter McGuire considers that this water is "without rival for all affections of the bladder and kidneys." A tumblerful must be given before each meal, or during the interval of the last two meals. Of course for the relief if not removal of the gouty diathesis upon which cystitis so often depends, it is necessary for the patient to continue the use of the Lithia water for several weeks, and at intervals subsequently during the spring and autumn months.

As the general health is usually impaired, attended by loss of appetite, insomnia, and neurasthenia when the active symptoms of cystitis have been relieved, the diet of the patient demands special attention. He should be well fed on rich beef soup—on Bovinine, a condensed extract of beef and mutton—a teaspoonful in a tumbler of new milk—and also take a malt extract, either Hoff or Wyeth & Bro., administered every few hours during the day and night. The plain soda cracker is the best form of bread. Of course, if able to incur the expense of resort to the mineral springs of Virginia or Arkansas, or to a sea voyage, the recovery may be permanent.

A PLEA FOR VENESECTION.

BY D. COLVIN, M. D.,
Of Clyde, N. Y.

As I believe it to be the duty of every medical man "to hold fast that which is good," and if perchance that which is good has seemed to have been lost, I consider it to be his duty to try and induce others to aid in regaining it, be it what it may.

I write this as a plea for venesection, which therapeutic aid seems to be so determinedly ignored. With no intention of speaking of its necessities in the various ills of life, I desire only to mention its use in two recent cases, to wit:

At 2 a. m. on the 3d of July last, Mrs. F., aged 52, and married, who had always possessed good health, awoke with difficulty of breathing, numbness of left side of face, and some of the remainder of the same side. Severe headache accompanied the numbness, and there was some confusion of intellect.

As I was not in the habit of going out at night, and she being quite partial to me as a physician, I was not called until early in the morning.

Upon my arrival, I was given the above history, and told that they (the symptoms) were changeable during the latter part of the night—at one time severe, forcing her to sit up in bed, while at another time she would be easier, nearly falling asleep. The pulse was somewhat irregular *as to frequency*, small and easily compressed; I believed there was a hyperæmic condition of the vessels of the brain, which, if allowed to go on, treated only with cathartics, aconite, and the bromides, would eventuate in a rupture of their coats.

I opened a vein with her in a semi-erect position, and allowed the flow to proceed (my fingers being *constantly* upon the opposite radial artery, which has always been my custom) until the pulse became *regular and fuller*, when she said, "My headache is gone, and I now feel as though I had a whole upper lip instead of half a one." (She had previously told me that when she put a glass to her lips the feeling was as though the left half of the upper lip was gone.)

After removing the ligature the blood continued to flow as freely as before its removal, requiring the compress and roller to be so tightly applied for a time as to obstruct the return circulation. Eighteen ounces were lost. This was followed by a saline cathartic *only*.

The following morning I found her doing her kitchen work (she was a poor woman), and I was saluted with the remark: "Doctor, I am well; the bleeding done it." She has been perfectly well since.

Case 2. Mrs. M., widow, aged 58, with health good generally, and a "hard worker," upon rising from her chair at the breakfast-table on the morning of the 16th of July last, suddenly discovered that her left side was numb, accompanied with intense headache. The left side of the face was especially numb.

I saw her in a few minutes, and found her suffering from the above symptoms: the suffering more especially was from the cephalalgia.

In this case the pulse was not irregular like the first, but firm and small. She was placed in a chair and a pint of blood was taken, when the pulse was observed to become *fuller* and softer, yet I allowed the flow to continue until the impression was decided. The same difficulty in arresting the flow was had as in the first case.

A cathartic *only* was given, and the following day Mrs. M. was about the house and feeling very well. No other medicines were given, and the numbness entirely disappeared in forty-eight hours.

Among the profession there seems to be such a horror of losing a little blood, that I wonder why those who are so tenacious do not at once seek to check the hemorrhage in every case of epistaxis or hæmoptysis to which they are called.

Notwithstanding the loss in these two cases, there was no evidence of it in the appearance or feelings of the patients on the following day.

Would aconite, the bromide of potassium, low diet, and cathartics, have averted the disaster which I believe the above symptoms indicated, as well as the venesection?

Medical Societies.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Semi-annual conversational meeting, April 22, 1886. The vice-president, James Tyson, M. D., in the chair. W. E. Hughes, M. D., Recorder.

Dr. George A. Piersol read by request a paper on

Medical Photography.

The character of photographical work which the medical man may probably desire to undertake may be divided into three groups: 1. Photographing specimens. 2. Photographing patients. 3. Photographing microscopical specimens, to which, possibly, a 4th should be added: making lantern slides and enlargements for the purpose of illustrating lectures. As to outfit, all of these requirements must be borne in mind. At the present time, possibly the best equipment for medical work would be one of Walmsley's modified copying cameras, as manufactured by the American Optical Company, taking a 4¼x5½ plate, fitted with a first-class lens. Regarding the latter, those desiring the best might limit their choice with advantage to the lenses made by Ross, Dallmeyer, or Beck. Personal experience with the Beck lens warrants a most favorable recommendation, as its superior qualities adapt it admirably to work requiring fine definition with great focal depth. As a matter of economy the excellent lenses of Darlot might be substituted for the higher-priced English glasses. As much less expensive the "Waterbury" outfit (camera, lens, and tripod costing but $14) is worthy to be considered. The addition, however, of a light wooden extension is imperative to obtain sufficient length of bellows to reproduce specimens of a normal size—a matter often desirable. A lens adapted for medical work would be a rapid rectilinear combination of about 8½ or 9 inches equivalent focus—a shorter focus lens possessing insufficient focal depth. In addition to the camera and lens, a simple dark room outfit, embracing non-actinic lantern, three trays, graduate, dust brush, light-proof box for opened packages of plates, and a few tubes, is necessary. Proper illumination is essential for satisfactory results. An evenly distributed top-light is most desirable. This can be obtained readily from a sky-light; such a convenience, however, is frequently wanting. An excellent substitute may be readily had by removing the apparatus to the open air, and stretching over all a piece of muslin, thus providing a mellow, evenly-distributed top-light, admirably adapted for photographing specimens. In focussing, the use of a focussing glass is advantageous. Focus without the diaphragm on a point lying midway between the extremes of the planes of the specimen; afterwards put in the smallest stop (say No. 128 F.=45.2 English scale). The small stop necessitates a rapid plate unless the exposure is unduly prolonged. A fast plate and small stop, when properly employed, yield pictures with the best possible definition and great focal depth, qualities very essential to satisfactory representations of specimens. In order to insure acceptable results, a correct exposure should always be attempted. The length of exposure depends upon many conditions. Among others, actinic power of the light, this being modified by sunshine or clouds, by time of day and by season of the year: color of the specimen—a tissue deeply dyed with blood requiring much greater exposure than the alcohol-bleached organ: character of the sun: size of diaphragm: sensitiveness of the plate: strength of the developer. Since these all modify the duration of any individual exposure, the oft-heard comparisons as to the bare numbers of seconds given upon various negatives are of very little import-

ance. Each worker must determine for his own conditions the exact number of seconds required on the ordinary specimens, and, with this as a basis, meet changing conditions as the occasion demands. While there are many excellent formulæ, the following developer has always answered admirably—with it, by slight modifications, all kinds of work may be satisfactorily performed:

No. 1.

℞.	Pyrogallic acid (Schering's),	1 oz.
	Sodium sulphite,	6 oz.
	Water,	48 f℥.

No. 2.

℞.	Sodium carbonate,	4 oz.
	Water,	48 f℥.

No. 3.

℞.	Sodium bromide,	1 ℥.
	Water,	1 f℥.

Use equal parts of No. 1 and No. 2 with 3 to 5 drops of No. 3 as a normal developer, the entire bulk of the developer being say 3 f℥. Remember No. 2 accelerates while No. 3 retards development; No. 1 giving density. A plate is fully developed when the deep shadows show some detail, and when the cardinal outlines of the picture show on the back of the plate with reflected light. The most usual failures result from over exposure and under development. When a plate blackens rapidly without the requisite amount of contrast between the high lights and deep shadows being at first present, we may strongly suspect over exposure. Pour off the developer, flood with water, and then proceed once more with a developer, to which say 20 to 30 drops of No. 3 have been added. The remedy for under development is evident. Strongly to be emphasized: select a good brand of plate, choose a reliable developer, and only change when there exists a strong reason for so doing; by this plan alone can the peculiarities and valuable qualities of any plate be learned. In addition to these fixed conditions, by at first employing but one lens and a single diaphragm, the path of the tyro is greatly smoothed. In photographing a patient, if possible, a skylight should be used; when, however, none exists, we can succeed fairly in any well lighted room, preferably one having two side windows. Opposite to window No. 1 and about four feet removed we place our subject almost parallel, facing the second window. The lower half of window No. 1 is covered with muslin, while over the upper half is partly drawn the shade. Window No. 2 (furthest removed from the patient, but toward which he looks) is unobstructed. The camera is placed somewhere near the second window. Some simple background should be improvised, and the darker side of the subject should be lighted up by a reflector of white muslin. Since the actinic power of light is immediately reduced within doors, our exposure would be unduly prolonged if we used the smaller diaphragms; we are therefore usually compelled to use the larger ones, Nos. 8 or 16. Photographing microscopical specimens requires a camera with a long bellows—24 to 30 inches. This may be had by adapting to the front of an ordinary camera an extension which may be readily constructed of wood, cardboard, or tin. The inner surface of the entire track of the light from the objective should be lined with black paper with matt surface. Any microscope admitting of a horizontally placed tube with a good stage and centering sub-stage may be employed. Likewise any objective possessing good definition and flat field may be made. The eye piece is best removed, the camera and microscope being united by simply inserting the draw tube into the extension of the camera and wrapping the joint with a few turns of some black fabric. Illumination is very important; four sources may be considered—lamp, calcium, electric, and sun light. Calcium and the arc electric lights, while quite satisfactory by way of experiment, are practically debarred by the expense and inconvenience attending their use. The incandescent electric light at the present time offers little advantage over good lamplight, and is far inferior to sunlight, It may be stated once for all that sunlight properly employed is the best possible illuminator for photomicrography. As it requires some care in its employment, and above all the devotion of the busiest hours of the day, we may inquire what can really be accomplished by lamplight. Mature consideration and considerable experience justify us in saying that with care and proper manipulation really good photographs may be made with powers up to the $\frac{1}{6}$; of course very much higher lenses may be employed, even the $\frac{1}{15}$ and $\frac{1}{18}$, but thoroughly satisfactory lamplight work with lenses approximating 1000 diameters is seldom if ever seen, One thing seems demonstrated beyond question: that with any power it is almost impossible to obtain the soft but brilliant micronegative, full of detail and vigor, that sunlight is capable of yielding. For lamplight, a lamp with a single moderately broad wick should be employed, the edge of the flame being turned toward the object. For very low powers, 3 to 1½ inch, no condensing lens is necessary. With higher powers the interposition of a 4-inch focus

plano-convex lens is advantageous, and with still higher lenses (say from ⅔ up) some form of sub-stage condenser in addition is almost imperative. After many experiments with various forms, a "B" eye-piece as a condenser seems to yield the best results, giving a powerful and evenly distributed illumination. Accurate centering and even distribution are of the utmost importance. First center the sub-stage condenser. Avoid "pushing" the illumination, as when the condenser is racked too high the margin of the field is destroyed. Experience teaches the advisability of using a slow "clean-working" plate (say Carbutt's "B") in preference to the very rapid brands. A mirror placed at the end of the work table opposite the ground-glass of the camera is of great assistance in adjusting illumination; a small hand-glass is also convenient to reflect the picture when hunting fields. The most important as well as difficult manipulation is focussing. With a short "pull," no especial requirements, but when a long camera is extended, removing ground-glass to 3 or 4 feet, some arrangement of moving adjustments is necessary. The simple arrangement with cord and weights which we devised eight years ago, and which has of late become extensively used, we still recommend as meeting all possible requirements. It has been put to the severest tests with powers of over 3000 diameters, and never has been found wanting either in delicacy or accuracy. A modification may be applied to the coarse adjustment. A focussing glass is indispensable; the point of most accurate focus is where the image seems to melt into the ground-glass. Preparations must be well differentiated and thin, possessing sufficient contrast and actinic opacity. In certain cases, by using glass of a complementary color to the stain, excellent results are obtained. While lamplight suffices for low powers, yet for the high powers and for difficult work, such as bacteria, sunlight by all odds is to be preferred. By arranging a simple mirror to swing laterally and vertically, we can substitute the necessity for a heliostat. Light from this mirror passes through a plano-convex lens of eight inches focus, through a cell of ammonio-sulphate of copper, to the sub-stage condenser. Here again accurate centering and evenly distributed illumination are absolutely essential for good results. To those aspiring to the best results, especially with difficult subjects and high powers, a trial of sunlight is strongly urged, as by this illumination alone are many of the capabilities of photomicrography rendered possible.

Succeeding his address, the lecturer exhibited on the screen about fifty examples of various kinds of work. Nearly half of these were photographs of pathological specimens; the remainder were photo-micrographs of histological and pathological preparations, taken with objectives giving from the lowest to the highest amplifications, among which an admirable photograph of the bacillus tuberculosis attracted much attention.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Thursday, June 3, 1886. The President, Dr. B. F. Baer, in the chair.

Dr. R. B. Harris read for Dr. Howard H. Kelly, now in Europe, a paper entitled

Gonorrhœal Tubo-Ovarian Abscess—Right Side—Laparotomy—Removal of Fallopian Tube and Ovary—Recovery.

(The paper will appear in full in the *American Journal of Medical Sciences.*)

In this case the disease of the woman could be directly traced to gonorrhœal infection on the part of the husband, although she had never, to her knowledge, had any uterine discharge other than blood, and had always been regular in her menses during the three years of her married life.

At fourteen, Mrs. H. commenced to menstruate; at seventeen, she weighed 135 pounds, although of medium stature, after which she failed somewhat in health from an abscess of a finger, and when married, at twenty, was quite spare, as was also her husband, both of whom are of German blood. The husband has since reached a maximum of 167 pounds. Three years before marriage Mr. H. contracted a gonorrhœa, of which he thought himself cured in three weeks. At the time of his wedding, however, he was suffering from orchitis, which he attributed to a strain, and which lasted for some time. The sickness of his wife commenced with her first menstrual epoch two weeks after marriage, at which time she had excessive abdominal pains, fever, vomiting and constipation, and was two weeks in bed; since which time she had repeated attacks of the same kind. She came under the care of Dr. Kelly on March 31, 1886, after having been under treatment for a supposed uterine fibroid during five months. After a month's preparation by enemata, vaginal douches and tonics, it was determined to operate upon her for the removal of a tumor located between the right side of the uterus and the pelvis, and evidently firmly attached in its

seat. This tumor had an elastic feel, had greatly affected the health of the patient by the production of menstrual prolongation and excess, and was evidently giving rise to symptoms of septicæmia. The tumor was removed May 5, 1886, and in separating it from its bed a small cyst containing fetid pus was ruptured; this necessitated irrigation and cleansing of the viscera with hot distilled water to avoid septic peritonitis. The pulse rose to 160 the next day, but fell in four days to 76, with a temperature of 98.8°. When examined after removal, the tumor, which was about two and a half inches in diameter, was found to consist of an ovary and dilated Fallopian tube, forming a common cavity filled with from two to three ounces of thin, greenish, highly fetid pus.

A drainage-tube was used for four days, the sutures removed in a week; the patient made a good recovery.

Ovarian Tumor.

Dr. T. M. Drysdale exhibited the specimen, and remarked: Five weeks ago I removed an ovarian tumor which, apart from the interest which attaches to each case of this kind, was personally important to me from the fact that it completed my one hundred and fiftieth ovariotomy. Twenty-five years since, April 23, 1861, I performed my first operation of this kind. At that time, as you are aware, the procedure was not in such favor in the profession as it now is, and the operators were few. In fact, I believe, I was the first, after the late Dr. Washington L. Atlee, who operated in this city.

My success has been encouraging. In each series of fifty, the mortality has grown less, and the results more and more satisfactory, but, as I expect to present a report of the whole number of cases to you in a short time, I will not now anticipate what will then be stated in regard to these results, further than to say that of the one hundred and fifty cases, I have lost twenty.

This tumor was removed from an unmarried lady, 20 years of age, who first consulted me in February for an abdominal enlargement. She was extremely thin and delicate-looking, but said she had enjoyed good health until attacked by the present disease; since then she had emaciated rapidly, her general health had failed, her stomach had become irritable, and her appetite deficient. She had an unnaturally red tongue and a feeble pulse, which varied from 110 to 140 beats in a minute.

She first menstruated when sixteen years of age, with great pain and excessive flow. Since then she had always suffered agonizing pain during menstruation, but had been regular until within the last six months; during this time she changed every two weeks, flowing for two or three days. For the last month she had a thin, sanguineous discharge every week.

She first noticed enlargement about eighteen months before I saw her. The whole abdomen swelled as if distended with wind, for which it was mistaken, her physicians treating her for a long time for dyspepsia. The increase in size had been very rapid in the last six months. On examination, the the abdomen was found to measure 37 inches around its greatest circumference, and was distended by a tumor of irregular shape and consistence. There was dullness on percussion everywhere, except in the epigastric region and over the right flank. No fluctuation could be detected except over a small portion in the left side about the level of the umbilicus, which was evidently cystic. A hard mass could be felt just below this, which appeared like an independent growth. On vaginal examination the cervix uteri was found to be small and flattened against the pubic bone by a hard tumor, which nearly filled the pelvis. This mass was found to be continuous with that which was felt to the left of the umbilicus. It was impossible to pass a uterine sound.

I diagnosticated a multilocular ovarian tumor. Assisted by my son, Drs. W. S. Stewart, John S. Stewart, and G. G. Chamberlain, of Middletown, Delaware, I operated April 28. On opening the abdomen the front of the tumor was seen to be covered by the right broad ligament, which was spread out to a great size and firmly adherent to it. The uterus was turned completely on its axis, and fixed by adhesions to the left side of the growths. A large trocar was introduced, but no fluid could be obtained until a cyst was reached high up on the left side. The remainder of the mass was composed of minute cysts and a nearly solid portion, which was that felt in the pelvis and left side before the operation. An incision was made in the wall of the tumor, and introducing the hand the interior was broken up as much as possible, yet it was difficult to reduce its size, and I was compelled to enlarge the abdominal incision to about eight inches in length before I could get the tumor through it. The adhesions to the broad ligament and uterus were then detached, as well as some omental adhesions; others to the wall of the right side of the pelvis still

held firmly. These were finally broken down, and the tumor, which proved to be of the right ovary, withdrawn. The pedicle, which was very thick and vascular, was secured by ligatures. From the surface of the adhesions there was an active and persistent bleeding, which gave considerable trouble, but this was controlled without the use of ligatures, except two to vessels deep in the pelvis. After thoroughly cleansing the cavity of the abdomen and pelvis, the wound was closed with wire sutures; a compress of absorbent cotton and a flannel bandage completed the dressing. I will not weary you with the details of her progress toward recovery. The only unpleasant symptoms she had were vomiting and violent colicky pains, which lasted at intervals for two days. Her highest temperature in the axilla was 101½°. Her pulse varied from 100 to 128. She has entirely recovered, and is daily gaining strength.

W. H. H. Githens,
Secretary.

CHICAGO MEDICAL SOCIETY.

OFFICIAL REPORT.

Stated meeting, June 21, 1886.

The President, E. J. Doering, M. D., in the chair.

Dr. F. E. Waxham read a paper entitled

Intubation of the Larynx as a Substitute for Tracheotomy, with a Report of 83 Cases.

The author referred to the various modifications that had been made in the instruments within the past year. First, the enlargement of the heads of the tubes to prevent slipping into the trachea; second, the addition of a shoulder to prevent their expulsion; and third, a very important modification consisting of the construction of the tubes with thinner walls, giving greater breathing space and a better opportunity for the expulsion of false membrane. The author also presented a feeding bottle useful in those cases where they entirely refuse to take nourishment, as they will do occasionally, and also a trachea forceps for the purpose of removing false membrane by way of the mouth when there is detachment below the tube, or when it is pushed down ahead of the tube and cannot be expelled.

The author thought that the first question that would arise, in considering whether we had a substitute for tracheotomy in tubage of the larynx, would be as to the comparative success of the two methods. By personal inquiry and by correspondence, he had collected reports of 306 cases of tracheotomy performed in Chicago with 58 recoveries, or a percentage of 18.95. The cases were as follows:

"One physician reported 3 cases with 3 recoveries; another 7 cases, 3 recoveries; another 33 cases, 9 recoveries; another 25 cases, 5 recoveries; another 30 cases, 6 recoveries; another 12 cases, 5 recoveries; another 20 cases, no recoveries; another 14 cases, no recoveries; another 8 cases, no recoveries; another 15 cases, 1 recovery; another 16 cases, 1 recovery; another 15 cases, 3 recoveries; another 9 cases, 1 recovery; another 1 case, no recovery; another 1 case, no recovery: another 4 cases, no recoveries; another 1 case, no recovery; another 3 cases, no recoveries; another 8 cases, 2 recoveries; another 1 case, 1 recovery; another 2 cases, no recoveries; another 5 cases, 1 recovery; another 3 cases, 1 recovery; another 4 cases, 1 recovery; another 1 case, no recovery; another 1 case, no recovery; another 3 cases, no recoveries; another 2 cases, 1 recovery; another 2 cases, no recoveries; another 4 cases, 2 recoveries; another 1 case, no recovery; another 3 cases, 1 recovery; another 2 cases, 1 recovery; another 5 cases, 1 recovery; another 3 cases, 2 recoveries; another 3 cases, 2 recoveries; another 1 case, no recovery; another 3 cases, 1 recovery; another 1 case, no recovery; another 2 cases, no recoveries; another 4 cases, 1 recovery; another 2 cases, no recoveries; another 2 cases, no recoveries; another 2 cases, 1 recovery; another 6 cases, 1 recovery; another 1 case, 1 recovery; another 3 cases, no recoveries; another 1 case, no recovery; another 1 case, no recovery; another 3 cases, no recoveries; another 2 cases, no recoveries; another 2 cases, no recoveries. Total, 306 cases, 58 recoveries."

In 138 cases the ages were as follows:

"One was 2 years and 2 months; 1 was 7 months; 1 was 13 months; 1 was 12 months; 1 was 20 months; 1 was 2 years and 5 months; 1 was 2 years and 3 months; 1 was 3 years and 3 months; 1 was 4½ years; 1 was 5 years and 7 months; 1 was 6½ years; 1 was 7½ years; 1 was 19 years; 1 was 24 years; 6 were 18 months; 9 were 2 years; 2 were 2 years and 4 months; 4 were 2½ years; 19 were 3 years; 7 were 3½ years; 14 were 4 years; 16 were 5 years; 3 were 5½ years; 16 were 6 years; 6 were 7 years; 8 were 8 years; 5 were 9 years; 4 were 10 years; 2 were 12 years; 3 were 13 years. This gives an average of 5 years and 1 month."

In contrast to these statistics, the author

reported 83 cases of intubation with 23 recoveries, or a percentage of 27.71. The ages were as follows:

No. of Cases.	*Age.*	*Recoveries*
1	9 months	0
1	11 months	0
1	13 months	0
3	14 months	1
1	15 months	0

7	——	0
83		23

Average age, 3 years and 7 months.

It will be observed that 11 cases with 3 recoveries were under 2 years of age; 28 cases with 8 recoveries under 3 years; 14 cases with 3 recoveries between 3 and 4 years; 15 cases with 6 recoveries between 4 and 5 years; 9 cases with 4 recoveries between 5 and 6 years; and 10 cases with 2 recoveries between 7 and 11 years.

Many of these cases were young nursing infants, and many were delegated to him because they were too young or too unfavorable for tracheotomy. Of the 58 cases coming under his own personal observation, 20 were actually moribund when the operation was performed, many of them entirely unconscious, and 40 were bad diphtheritic cases, characterized by severe constitutional symptoms and extensive diphtheritic exudation upon the pharyngeal walls. In only 18 cases was the exudation in the pharynx slight, but in every case, without exception, membrane was expelled either in the form of thick muco-pus, shreds, or large casts. In every case the operation was performed to prevent impending suffocation, and the cases pronounced hopeless without surgical interference.

Dr. D. A. K. Steele, in opening the discussion, said that of course the principal interest to the surgeon centres in the question of the performance of tracheotomy in croup or diphtheria. I have looked up some of the older statistics, in addition to those given by Dr. Waxham. The French seem to have led the way in the practice of tracheotomy. Trousseau, in 1858, gave the statistics as about 25 per cent. of recoveries, and from later reports tracheotomy does not seem to have gained much. Dr. Solis-Cohen, of Philadelphia, in 1883, recorded some 5,000 cases, and his per cent. was the same as given twenty-five years before by Trousseau, about one in four. More recent statistics show some improvement in tracheotomy; for example, Dr. Jacobi, of New York, published 1,000 cases in which he had a little better success, if I remember correctly, than those reported by Solis-Cohen. A few days ago I saw a report of seventy-seven cases from the Boston City Hospital, with a recovery of twenty cases, about 25 per cent. In Chicago the statistics, as given by Dr. Waxham, are 306 cases with a recovery of about 19 per cent.; these are the most recent statistics I have found. Of course, in regard to the report of cases of tracheotomy, we have to bear in mind a very practical point—that is, that the unfavorable cases are not all reported. The majority of physicians who do a few operations and have not a successful result, do not record their cases. In New York city some twelve years ago a surgeon reported 67 cases with 13 recoveries. He made operations on 100 additional cases before he had another successful one; so there are curious mixtures and changes in the statistics of different operators.

Another point is that a good many surgeons report as successful cases all that recover from the operation, but that die of some other affection or sequela, as this case reported by Dr. Waxham dying from albuminuria; all these cases are reported by tracheotomists as recoveries; but they are not recoveries from the diphtheritic croup. These points must be borne in mind. When we sum up, the statistics to-night would show a recovery of 27 per cent., which certainly seems to me to be a very favorable showing. In addition to these cases reported by Dr. Waxham, Dr. O'Dwyer has of late recorded 25 cases with a recovery of 24 per cent.; taking all those cases into consideration, the Chicago record is ahead of the New York record by 3 per cent. In regard to the Boston City Hospital, where they had 25 per cent. of recoveries, we should bear in mind that those cases presumably have much better surroundings than we have in Chicago, or in general practice. There they have the

best of nursing and immediate attention in case any mishap occurs, which in some cases in private practice might go unnoticed for many hours. With the favorable surroundings so far as the operation and the after-treatment are concerned, the reported recoveries of 25 per cent. are as favorable as we could expect.

Intubation is a comparatively new operation, but with the improved tubes (a serious defect in the construction of these tubes has been that the lumen was too small), I think that by enlarging the calibre of the tubes the percentage of recoveries would be increased. There would be less danger of rolling up the detached pieces of matter, and I think that expectoration would occur more freely. It is supposed to be necessary to have the tube extend down near to the bifurcation of the trachea, so as to prevent the curling pieces of membrane blocking up the opening, but I think they are longer than is necessary. The principal obstruction, we know, is at the larynx; the membrane below the trachea is thinner, smaller, and is not likely to curl up in this way. Theoretically the tube should be long, practically it might be shortened, and with the improved tubes we will get still better results.

A point in favor of intubation over tracheotomy is the rapidity with which it can be done, taking only the fraction of a minute to insert a tube in the hands of an experienced operator. We might also take into account the greater comfort of the doctor after the operation—the feeling of security with the laryngeal tube. I am constantly in dread after tracheotomy, watching and waiting, and seeing the little patients upon whom I have operated die one after another. Then the relief from dyspnœa seems to be quite as great after intubation as after tracheotomy. The relief from urgent symptoms is just as marked with the introduction of the laryngeal tube as with tracheotomy. In case we find intubation does not afford permanent relief, it is no bar to tracheotomy subsequently, although where intubation does not relieve dyspnœa, tracheotomy will not relieve it; where stenosis is not relieved by the introduction of the tube, it does not relieve the dyspnœa.

Dr. W. E. Casselberry said his experience either with intubation or with tracheotomy has not been very extensive, but from it and from what he had gleaned from the literature of the subject, including the valuable paper presented to-night, he was very favorably impressed with the operation of intubation. The most favorable statistics of tracheotomy are those of not only the French, but more particularly of the large hospitals of France and Germany. In these institutions they have the fullest command of the patients in every way, the greatest attention can be paid them, and the operation can be and is performed early. The most favorable statistics are those of Plenio (Konigsberg)—and of all the cases that were taken to the hospital but five escaped tracheotomy, showing that almost all were subjected to the operation. The case of Dr. Ingals, in which the membrane was removed from one of the bronchial tubes, was a most brilliant one, but then intubation does not prevent tracheotomy from being performed afterwards. The forceps for the removal of the membrane through the mouth which the author has exhibited this evening is new; I have not much confidence in it, but perhaps it may be of value. In reference to the length of the tube, somebody has proposed that it should be shorter. I think it is the length of the tube which has rendered this operation successful over the operation of some eighteen or twenty years ago. It was invented by a French surgeon at that time, but the tube was only about ¾ of an inch long, sufficient only to reach into the larynx, where it excited irritation, and the operation was discarded as of no value; so that I think in the length of the tube we have an important feature. In reference to the introduction of the tube, if it is possible to practice on the cadaver it would be of great value; a minute is a long time when you are introducing a tube into the larynx of a child who is suffering; you gag the mouth, introduce the forefinger as a guide to the larynx, follow it by the tube; the child stops entirely the feeble respiration, in a few seconds he becomes black in the face, and you are very anxious either to get the tube in or your finger out. If we bear in mind the instructions of the author of this paper to pass the tube under and not over the forefinger as a guide, I have no doubt we will be successful. And recollect that the curve into the trachea is a right-angled curve, so you must turn acutely and not obtusely, or you will enter the œsophagus and not the trachea. The food of the patient is a most important point; when the tube is in, liquids will frequently run into it and excite irritation.

Dr. A. B. Strong said: Before coming here I was prepared to endorse this operation to a great extent. I did not suppose the statistics were so favorable, but I am glad to find they are so. I have had quite a number of cases of intubation and of trache-

otomy, and I must say I much prefer the introduction of the tube. However, not every case is adapted to the intubing; I think there are many cases where tracheotomy would be far preferable. We can feed a little patient after tracheotomy much better than after intubation of the larynx; to introduce a stomach tube would require the attendance of the physician several times a day. I have not yet given a fair trial to introducing the food into the rectum. I should not want a little patient that had suffered for three or four days before the operation to go without food; I like to feed my patients well, and certainly would not wish to starve them. There are three or four cases that have given me a good deal of information. The operation is new; we do not know all there is about it. One of the first cases that I had of true diphtheria, where intubing was done, was a little boy four years of age, taken sick five days before I saw him. The physician in attendance had given the child up, and I was called in. The little fellow was as near dead as any patient I had seen, but I would not have recommended tracheotomy in that case. The neck was badly swollen. Patient was cold, clammy, pulseless, and cyanosed. Pupils widely dilated; apparently just on the verge of dissolution, mainly from profound blood-poisoning. I introduced the appropriate tube, and much to my surprise I nearly strangled him; indeed, for a moment I thought him dead. I drew the tube out, and the child breathed a little bit better. It occurred to me that I might have crowded the membrane down. I introduced the tube again, with the same result; he was nearly strangled. I tried a smaller tube, but each time the tube went in the child nearly died. I laid him on the bed and surrounded him with dry heat. Brandy hypodermically. I did not suppose the child would live more than an hour, but to my surprise I received a telephone message that he was alive and doing well ten hours afterward. I went to see him and found him with a good color, taking considerable nourishment. I called again in six hours, just in time to see the child die. I had the privilege of post-mortem, and found exactly the condition of affairs I had anticipated. At the lower portion of the trachea I found a complete cast of that membrane crowded down. This case had been going on about five days when I saw it, and this membrane had been loosened in the meantime and so crowded down.

Another case was of a good deal of interest. A little girl, eight years of age, had a mild attack of diphtheria four days prior to my seeing her. Two days before I saw her the larynx first became involved, and gradually grew worse. The case was one of the most favorable for operation that I have seen. We introduced the largest sized tube, and it remained in position for three days, and within twenty-four hours the lungs cleared up very nicely; at the end of three days and two hours the tube was removed with comparative ease, and I noticed that the child did not breathe as freely as I supposed she would. I remained about an hour, and during that time dyspnœa set in and the child nearly choked to death; we put in the one next in size, and the symptoms were instantly relieved. The child wore that tube two days, when it died from bronchitis.

That case gave me this idea: the tube first introduced was as large as the parts would readily take in—it required a little force to introduce it—and it occurred to me that the tube was larger than was necessary. It remained there three days and two hours, squeezing the blood out from these parts, and when it was removed the sudden reaction caused the œdema of the larynx. The child wore that tube five days and a few hours, and until the last twelve hours of its life was getting along very nicely, except that it did not take the amount of nourishment I considered necessary. The operation is brilliant, and has a future before it, and I can heartily endorse it to-day. I am perfectly willing to try it, and I would prefer, in case of one of my own children, intubing the larynx to opening the windpipe.

Dr. Christian Fenger said: The subject is a most important one. As to the history of the operation, I would say that it is not a new one. A French surgeon, Loiseau, invented it in 1858, and to him belongs the idea. The instruments were, in principle, about the same which we use now; there have been modifications in details only. Tubage was tried in France by Gros, but seems not to have found favor, although Bonehut recommended it without having used it himself. It was tried in Vienna by Weinlechner, who recommended it, condemned by Steiner and Ziemssen, and given up again. In reference to what was said about patients not swallowing at all for the first twenty-four hours, it seems to me it would be difficult to keep little children from drinking milk, or water perhaps, milk anyway, because they are always thirsty. There will thus be danger from foreign-body-pneumonia (Schluck pneumonie). It might be that feeding bottles will obviate that danger. A second point is this: I saw a child treated

by intubation die from loosened membranes closing the bifurcation. Whether the membranes were entirely loose or not, or loose above and attached below, is not materially important. The case convinced me that I would have felt safer with tracheotomy, because loosened membranes can be reached easier through the tracheotomy tube than through the larynx. As to the statistics, it is quite certain that the tracheotomy statistics are a little better than have been given here to-night. In the large hospitals in Germany the recoveries reach up, in the last few years, to 31 per cent. At the same time, when intubation shows 27 per cent., that is in itself reason enough for a trial. All these points are not exactly or exclusively in favor of intubation, but like Dr. Strong, I should first try the tube, if it was my own child, and watch the patient incessantly, with the tracheotomy instruments on the table to be ready at any time when needed to resort to tracheotomy.

Dr. S. Stockton was in favor of intubation.

Dr. R. G. Bogue said: There is much to recommend intubation, I believe.. The testimony we get is certainly enough to recommend the operation, and to establish it as a practical procedure and one worthy of trial. It affords probably as much relief for the urgent symptoms, the ones for which tracheotomy would be resorted to, as tracheotomy would; and the length of time that the tube is to be worn will be shorter than the tracheal tube. There are reasons why it should; from the pressure of the tube upon the membrane its presence would be likely to cause some disintegration of the membrane, and in that way the membrane would be taken away or gotten rid of sooner than without the pressure. The only objection—at least the one objection which occurs to me from what little I have seen, and what we hear—is the matter of fluids passing through the tube into the trachea and into the respiratory passages while attempting to feed the patient. That is an annoyance, and probably a detriment. It also, I suppose, will deter children from trying to take fluids. Little children soon learn to avoid things which hurt them, and I should think that it would be a factor in preventing the free feeding of children. Now it may be that the introduction of fluid into the air-passages may not be harmful, for as recently as to-day I saw in some report from New York the recommendation, in case of tracheotomy, where there is obstruction below the tube, to pour fluid, by teaspoonful, for instance, into the tracheotomy tube, letting it run down into the air-passages for the object of liquefying and softening the membrane and getting rid of it in that way. That I think is recommended by Dr. Geo. F. Shrady, who had practiced it recently with apparent benefit.

(*To be continued.*)

Editorial Department.

Periscope.

A New Method for the Detection of Hyaline Casts.

Dr. S. E. Armstrong, of Passaic, N. J., sends to the *Med. Record* a description of a method of manipulation devised by him to facilitate the detection of hyaline casts in the urine. He calls attention to the value of these casts from a diagnostic point of view, since the presence of albumen alone is no certain evidence of the existence of nephritis, and its absence does not necessarily imply a healthy state of the kidneys. He writes: "The hyaline cast may be said to form the stroma of all other varieties—the oily, epithelial, granular, etc. It is always found in some of the different stages of any of the forms of Bright's disease, particularly in the first stage, when a recognition of the trouble is most to be desired. The propriety of making a positive diagnosis on the strength of this one sign may justly be questioned, but there are usually other symptoms, objective or subjective, to aid us. Of course, the use of the microscope in the search for hyaline casts is an absolute necessity. Two methods are usually taught, viz., staining, and tilting the mirror. The first I regard as impracticable, because it involves too much trouble; the second, because it is unreliable. I have never been able to make the desired success of either, though I must confess that I have not frequently tried the former. There is another method, which comes to me in the nature of a discovery. Others may have known of it for years; I have not been able to find a description of it in the books, although it may be there. Briefly, it consists in preparing the specimen in the usual way,

between a plain slide and cover-glass: then placing the slide in position and adjusting the focus, the observer, with his eye at the instrument, presses the cover-glass down with a thumb on either side of the objective, and then, the slide being firmly held by the clips, pushes the cover-glass a little bit forward and back. By this means he has the advantage of *looking for an object in motion;* also, a cast, if present, is made to pass, rotating on its long axis, through different planes of the fluid, *hence through different possible foci.* By this means alone it is almost sure to be discovered. But there is still another advantage in this method, viz., as the cast revolves through the liquid it gathers on, perhaps amorphous urates, vibriones, or whatever minute object it comes in contact with, and is thus brought out into bold relief. Of course, we must by previous examination exclude granular casts, otherwise *after* manipulation we may be puzzled to tell which variety we have discovered; we must also be sure we have not rolled out a white blood- or pus-corpuscle, so that it misleads us into the belief that we have found a short one of either one or the other variety. Prolonged manipulation is neither necessary nor advisable."

The Surgical Treatment of Subinvolution.

Dr. A. Palmer Dudley thus writes in the *N. Y. Med. Jour.*, September 4:

"These patients were at once put upon the use of hot vaginal injections twice daily. If there was cystic degeneration of the cervix, all of the cysts that could be reached were tapped. If the os and cervical endometrium were granular, appropriate treatment for it was given; and applications of Churchill's tincture of iodine to the cervix and vaginal roof, together with glycerin tampons, were used in some cases as often as every other day. That this method of treatment was beneficial no one for a moment could doubt, but it did not cure my patients. It did not relieve the weight and dragging pains, or do away with the foul leucorrhœal discharges of which the patients had so long complained.

"After each patient had been kept under this form of treatment for a certain time, she was put under an anæsthetic, and the depth of the womb carefully noted. If menorrhagia had been her habit, the cervix was rapidly dilated and the endometrium carefully but thoroughly curetted with Bozeman's curette, and then touched with a 1 to 2,000 solution of bichloride of mercury, wiped dry, and again touched with glycerite of carbolic acid. Many prefer the use of Churchill's tincture of iodine for this purpose, believing it more efficacious in preventing a return of the fungosities; but, in cases where the cervix is to be operated upon, the use of the iodine is disadvantageous on account of its discoloring the parts and rendering the operation more difficult. After this treatment of the endometrium, if the cervix was lacerated, I operated for its closure after Emmet's method, going deep into the angles of the laceration. If the cervix was not lacerated, I operated after the following manner: I steadied the cervix with a heavy, curved tenaculum, and, with a pair of sharp, narrow-bladed scissors, I made a deep, narrow, V-shaped incision in each side of the cervix, extending the incision, if possible, deep enough into the uterine tissue to sever what we ordinarily style the circular artery. Then, after letting the incisions bleed quite thoroughly, I closed the wound by passing sutures from without inward across the incision, taking care that the first sutures ligated the several vessels. After the operation, warm water vaginal injections were used for cleanliness only. If the uterus was retroverted, a pessary was fitted and allowed to remain in position while the wound was healing."

The results were satisfactory.

The Treatment of Irritable Brain and Congestion of the Brain in Children.

Dr. William H. Day thus writes in the *Medical Press*, August 11:

A favorable result depends in a great measure on meeting the symptoms with promptitude at the outbreak, when there are only slight headache, alteration of manner, and disturbed sleep, to guide us at that early stage when it is impossible to say what is the essential cause of the trouble, what is its exact nature, and what is its probable termination.

Rest in these cases of irritable brain is to be strictly observed, since it checks the over-expenditure of nerve-force by conducing to repose and sleep. The brain being sensitive, exhausted, and easily fatigued, absolute rest is as much needed for its recovery as it is for a broken limb or a dislocated joint. This simple precaution is seldom sufficiently insisted upon until it is too late. Strong light, noises in the room, and the presence of anxious friends, tend to excite these young patients. Through the medium of the nervous system the circulation becomes disturbed. Physiological rest tranquilizes the circulation, allays excitement, and favors recovery.

If the head is hot (and this belongs to the *congestive* rather than to the irritative class), a cold lotion or ice-water rags may be applied to it. Cold continually applied to the head will often induce tranquillity and sleep, when bromide and chloral fail. Cold soothes the patient. If we dread the approach of meningitis, henbane, and even small doses of morphia in combination with hydrate of chloral, will prove of the utmost benefit in the early stages.

An aperient will generally be demanded. A grain of calomel, followed by a little syrup of senna, or by a few grains of sulphate of magnesia and nitrate of potash, will answer well, if the strength is good, and there is any heat of head. After this some bromide of potassium, with small doses of the iodide or hydrate of chloral, according to circumstances, should be given regularly. When the symptoms of cerebral congestion predominate, the bowels can scarcely be kept too open; and if there be arterial tension, aconite in combination with the bromide will tend to reduce it, and calm the excited brain at the same time.

The feeding of these cases is important. It should be nourishing from the first, and in the absence of vomiting (which we have noticed in all the cases) milk and beef-tea are to be freely given. Food from the first, in a nourishing and readily assimilable form, should be given.

The Detection of Chronic Bright's Disease.

After referring, in the *Medical News*, August 28, to the fact that the presence of tube casts is often overlooked, Dr. C. W. Dulles says:

The discovery of the tube casts, which escaped another, and perhaps several examiners, may have been due to the method of examination which I employ, and it is chiefly to call attention to this that the account of the present case is published.

In the first place, I am strongly impressed with the advantage of allowing the sedimentation of a specimen to take place in a straight glass, and not in a conical one, as is recommended in most of the books. In the latter, I think, one may easily miss a few tube casts, because they are not heavy enough to resist the attraction and friction of the sides of a conical glass, and so never find their way to the bottom. For this purpose a test-tube with a foot, I think, is the best receptacle.

Another point to which I desire to call attention is the plan I have devised for catching a specimen of sediment for microscopical examination when the deposit is very slight. After leaving the urine to settle in a test-tube with a foot for twenty-four hours, under a paper cover pressed down upon and around the top of the tube, I take a long, pointed glass tube, close the upper end firmly with my finger, and, pushing the point through the centre of the paper cover of the test-tube, thrust it steadily to the bottom of the urine. I now remove my finger, and the bottom layer of the urine, containing the deposit of twenty-four hours, flows up into the long tube. When it has risen to the level of the urine in the test-tube, I carefully twist a piece of soft paper over the upper end of the second tube, or stuff a small bit of absorbent cotton into it, to keep out all foreign substances, and allow the apparatus to stand undisturbed for twenty-four hours or longer, during which the deposit contained in the column of sediment falls to the bottom of the smaller tube. At the end of this time I close the upper end of the smaller tube firmly with a finger, withdraw it carefully from the test-tube, and then allow the two or three drops nearest its point to run out on a slide, in two or three places, cover them properly with thin glass, and put them under the microscope.

Cachexia Strumipriva.

The records of cases in which a condition resembling that of myxœdema has developed after extirpation of the thyroid gland are increasing. The latest is an account furnished by Dr. Hans Schmidt, of the Augusta Hospital, Berlin (*Berl. Klin. Wochensch.*, 1886, No. 31). It appears that during the five years 1880–86, twenty-five cases of thyroidectomy have occurred at this hospital, mostly under Professor Küster's care. Of these, six were cases of total extirpation, seventeen of unilateral, and two of malignant growths. All the unilateral cases survive, and not one of them has developed any ulterior symptoms, the interval since operation varying from six months to four years. Of the cases of total extirpation, two died of hemorrhage following operation, another died about a year later from phthisis, another patient, a young girl, was perfectly healthy several years afterward, and a fifth required tracheotomy six months after the thyroidectomy, on account of paralysis of the abductors. In only one case had the manifestations of cachexia strumipriva arisen. This was a lad who, at the age of fourteen years, was admitted in July, 1883,

suffering from an enormous goitre, which caused considerable dyspnœa. The operation had to be done in two sittings, and on each occasion tracheotomy was necessary, the canula being removed the day after. After the lapse of two years and three-quarters he was brought to the hospital by his father, with the statement that ever since the operation he had gradually deteriorated both mentally and physically, leading a listless, indolent life, taking no interest in anything. The change in the lad's physique was most striking, and thoroughly accorded with Kocher's description. The body was undeveloped, the muscles were lax, the skin flabby and of a yellowish color; there was slight œdema of the cheeks and back of the hand; the mucous membranes were pale, the testes very small; no splenic enlargement existed. The trachea appeared to be very thin, and there was no trace of a thyroid gland. The head was relatively large, and hair scanty; speech slow and drawling; aspect stupid and dull. He walked slowly, and was easily tired. The larynx and urine were normal. His memory had become defective.

Case of Unusually Large Calculus Removed from a Girl per Urethram.

Mr. Andrew Boutflower thus writes in the *Lancet:*

H. H——, aged twenty-one, was admitted on January 11, 1886. She complained of total incontinence of urine, accompanied with great pain. On examination, a very large calculus was felt through the vaginal wall of the bladder. At the age of ten she suffered from morbus coxæ; abscesses formed in the groin and gluteal region, with extensive sinuses, frequently discharging small pieces of bone, which had for a long while been completely healed. Since that time she had been perfectly well, with the exception that twelve months ago she menstruated irregularly, and had to get up frequently at night to urinate, which was always accompanied with difficulty and a bearing-down pain. This condition gradually became worse; the urine became white and thick, and had to be passed every hour; latterly complete incontinence had supervened.

When admitted she was much emaciated; the urine was alkaline, with heavy phosphatic deposit. An operation was performed on January 16. After rapid dilatation of the urethra with the fingers, the intention was to introduce a lithotrite and crush, but this was found difficult to accomplish. The bladder was tightly contracted round the stone, and injection of the bladder was useless. Owing to this contracted condition it was found impossible to grasp the stone with a lithotrite without including mucous membrane. A pair of lithotomy forceps was therefore introduced, and with gentle traction, but not without considerable difficulty, the stone was extracted, the procedure causing some laceration of the urethra. The stone weighs $2\frac{1}{2}$ oz.; it measures $2\frac{3}{8}$ inches in length by $1\frac{3}{4}$ inches in width, and is nearly 4 inches in circumference.

For the first ten days after the operation the patient progressed most favorably; after this some septicæmic symptoms developed, but these have passed away, and she is now quite well. Some degree of incontinence still exists, but it is hoped that this discomfort may gradually subside.

Remarks by Mr. Boutflower.—It is always easy to be wise after the event, but I have no hesitation in saying that if such an unusual case ever came under my care again, I should certainly remove the calculus either by the suprapubic or vaginal lithotomy.

Third Stage of Labor, with Special Reference to Retained Placenta.

Dr. H. C. Hendrick thus concludes a paper in the *Med. Times*, September 4:

In the resumé of our subject concerning the third stage of labor, we would recommend ordinarily:

1. That efforts to deliver the placenta should be made within the first ten minutes following the close of the second stage, believing the vigorous uterus more responsive then than at a later period.

2. That the application of the binder prior to the delivery of the placenta, except in inertia of the womb and delay when the accoucheur could not remain by the side of his patient, is not only useless, but a hindrance.

3. That neither mode, of traction alone or expression alone, is the most efficient or desirable means of aiding in the delivery of the after-birth; but if either mode alone is to be adhered to, that of expression has the advantage over traction in being the more efficient in completing this stage of labor, and also in preventing hemorrhage.

4. That the best method known is the proper combination of the two methods (traction and compression) combined, keeping in remembrance that there is a vast difference between pressing the uterus and compressing or grasping.

5. Never neglect maintaining the firm

grasp of the uterus for a period of some minutes following the descent of the placenta.

6. That the best treatment of retained placenta is not to have it; but, having it, to proceed with artificial delivery as soon as practicable; better use the most efficient means that can be deemed judicious than to leave the patient with the greater risks of hemorrhage. and a subject of adynamic and ataxic fever.

7. The best treatment of retained placenta in abortion is to "go for it" as promptly as possible.

Plugging the Trachea in Lesions of the Pneumogastric.

In an article in the *Nordiskt Mediciniskt Archiv.*, Dr. Jens Schou, of Copenhagen, discusses at some length the treatment of traumatic lesions of the pneumogastric nerve by means of permanently plugging or tamponing the trachea. Dr. Schou gives a succinct description of the doctrine propounded by Traube, that the pulmonary affection caused by section of the pneumogastric nerve is a pneumonia by aspiration—a theory which has lately been supported by other observers, more especially Gärtner. It appears that with animals the unilateral section of the pneumogastric or of the recurrent nerve is generally harmless; but in the human subject it causes pneumonia by aspiration. The reason seems to be that in animals the sections are effected without complications, whilst in men they are as a rule the result of some serious operation capable alone of causing a state of collapse from which pneumonia by aspiration might result. Here, one of the vocal cords is paralyzed, which serves to increase the effect of the lesion. The treatment indicated is, then, permanent tamponing of the trachea till the end of collapse, by which time the healthy cord will be accustomed to replace the diseased one. Below's method—namely, tamponing above the cannula—is recommended, an india-rubber ball above. Dr. Schou, however, prefers to introduce a tampon of some antiseptic material, such as iodoform gauze. A tampon of this kind is easily applied by means of a cannula open above. If it be necessary to cut the pneumogastric or recurrent nerve, tracheotomy and tamponing should be immediately resorted to, in order to prevent the development of pneumonia by aspiration. Should some time have elapsed before pneumonia by aspiration fully developed has been discovered, it is still necessary as quickly as possible to do the tamponing, in hopes of arresting the progress, for in these cases the nerve may be paralyzed for some time.

Blood Catheter.

De F. Willard thus writes in the *Med. Times:*

Many a physician has been foiled in his attempt to empty a bladder of urine by the persistent clogging of the eyes of the instrument with coagula, whenever even slight difficulty of entrance has been encountered.

The instrument I use has been put to thorough and practical tests, and has proved itself to possess the following advantages in all cases where trouble is expected during introduction, or even where slight hemorrhage is probable:

1. Its eyes are two or three times the ordinary size.

2. It is carried into the bladder with the eyes closed, thus preventing choking of the apertures during the slow and often difficult passage along the urethra or through the neck of the viscus.

3. The obturator or plug can be rotated *in situ*, or slid backward and forward so as effectually to clear the openings.

4. The rapid withdrawal of the obturator loosens the clot by suction.

5. The obturator can be reintroduced and manipulated as frequently as necessary, without the slightest injury to the patient.

6. If desirable, injections into the bladder can be made through it, or a Bigelow Evacuating Apparatus can be attached to remove large accumulations of blood or of clots in the bladder.

The instrument, as made for me by Gemrig, of Philadelphia, is of any desired size, the apertures being large, and the interior of the tube being accurately filled with a sheet-metal spirally-coiled obturator or plug, which is very flexible and moves easily in all directions.

Fracture of Zygoma.

A case of this rare nature was reported in the *St. Louis Courier of Medicine* for August. Anthony McGrath, æt. 24, laborer March 29, while carrying a bucket of mortar up a ladder, in endeavoring to step to the roof of a dwelling, fell head foremost thirty-five or forty feet, through the joints of the building, striking the side of his head, in his descent, upon a projecting joist on the second floor, and falling through to the ground floor. Remained half unconscious for some time, but received no special attention that day; came to the clinic the following day, complained of diffi-

culty in opening his mouth, together with severe pain, which was more or less constant, and aggravated by motion of the inferior maxilla. The teeth could only be separated sufficiently to allow a lead-pencil to be placed between them. Further examination showed some orbital ecchymosis and a bruising of the left side of the face and head. Considerable swelling had taken place, but a marked depression existed over the zygomatic arch. This depression was recognized as a fracture of the zygoma. The fracture must have been somewhat comminuted, for a crepitus was elicited. The crepitus was wanting in the characteristics of the false crepitus of effusion, and was appreciable to the patient as well as to others. The integument over the arch was intact, but very much bruised. The orbital ecchymosis was quite pronounced, and unaccompanied by cerebral or other symptoms. The treatment in this case consisted of absolute fixation of the lower jaw until the swelling had subsided, and in a few days movements of the jaw practiced. Within two weeks the patient could open his mouth sufficiently to permit the introduction of two fingers (one superimposed upon the other) between his teeth. The patient continued to do well, and was lost sight of shortly afterwards.

Nitrate of Potassa and Mercurial Inunctions in Acute Rheumatism.

In the *Russkaia Meditzina*, No. 15, 1886, p. 260, Dr. L. Grinevitzky, of Rostov-on-Don, eulogizes the treatment of acute articular rheumatism by the internal use of nitrate of potash (two drachms daily, in a solution with raspberry syrup, a tablespoonful every two hours), and by the inunction of a mercurial ointment. (The author's formula is this: R. Ol. hyoscyami, ʒj.; ung. hydrarg. cinerei, ʒij.; ext. aconiti, ʒj. M. To rub in the joints affected every morning and evening.) Fever gradually abates; the pulse becomes less frequent; articular pain, swelling, and heat decrease. The patient recovers in one or two weeks, according to the severity of the disease, and its duration before coming under treatment. When resorted to in the very beginning of the affection, the treatment prevents spreading of the latter to other joints, or, at any rate, mitigates any subsequent symptoms. The author's assertions are based on an experience of more than twenty years' duration. None of the other old or new anti-rheumatic remedies can compete with nitrate of potassa, as the author says. Frictions alone only somewhat mitigate the symptoms, but do not cure the disease, while the salt alone acts well, though recovery then becomes more protracted than where the inunctions are employed simultaneously. In conclusion, Dr. Grinevitzky states that, for the sake of comparison, he tried to treat some cases of rheumatism by nitrate, carbonate, and subcarbonate of soda, and by carbonate and subcarbonate of potassa, and "did not obtain from them any use whatever."

A Subcutaneous Method of Treatment of Buboes.

Dr. Scott Helm read a paper on this subject before the Chicago Medical Society. His method consists in injecting the suppurating gland, after the pus has been withdrawn, with a solution of carbolic acid to wash out the cavity, and then injecting, and allowing to remain, an emulsion of iodol in pure oleic acid. The injecting instrument consists of a barrel holding two drachms, which is mounted on either side by two rings for the fore and middle fingers, and a ring in the end of the piston for the thumb. Three needles, two different sizes of aspirator needles, and one a cannula with trocar. To these is attached the centre joint, in which is a stop-cock, the opposite extremity of which is attached by a smooth joint to the barrel.

In twenty-three cases, the treatment was successful in all but the nineteenth, this patient having gone on a protracted spree following the operation. The advantages of the operation are that when there are two or more suppurating buboes in the same chain of lymphatics, the second or third appear further away than the initial one; by placing the first glandular abscess in a perfectly septic condition you prevent the inflammation of neighboring glands; secondly, there is no cicatrix remaining.

Foreign Substance in the Uterus.

Dr. W. E. Hughes thus writes to the *Med. Age:*

Some months ago I was called some distance away to see Mrs. M., and meet there her family physician.

History of case as follows: She had failed to menstruate for some weeks, attributing her failure to closure of the womb. Was advised by a female friend near by to "open the womb," which she proceeded to do with a hair-pin. By some mischance she let it go, and it slipped into the uterus. Failing to remove it, she became greatly alarmed and sent for her family physician, who, after much

trying, also failed to bring it down, and sent for me to try. I introduced a speculum and with a sound succeeded in bringing down one branch of the pin, grasped it with long slender forceps, and with the sound disengaged the other end. A few drops of blood followed. She of course felt very much relieved. What followed is the peculiar part of the story. Happening to be in the neighborhood about five months after, I was told that she had been safely delivered of a fine boy a few days before.

Considering that the three-inch hair-pin had been in the uterus for thirty hours, and that first and last the uterus had been somewhat roughly handled, it is reasonable to suppose that the baby had a very narrow escape.

Electrolysis in Stricture of the Urethra.

Dr. F. O. Marsh thus concludes a paper in the *Cinn. Lancet and Clinic:*

1. No appreciable amount of heat is developed in any metallic electrode imbedded in the living tisssue. Even if such were the case, the cautery could be no more destructive or painful than the molecular rending of the part by electrolytic action.

The choice of metal for needles or electrodes, or the selection of a special galvanic battery, is a matter of indifference, as far as the heat produced in the tissues is concerned.

2. The use of electrolysis for division of urethral stricture is unsuitable, being excessively painful and ineffectual. The passage of deep stricture with a mild current must be due to some other influence—perhaps the continuous pressure of the instrument upon the face of the stricture.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The Fifth Registration Report of New Hampshire, for 1884, gives ample statistics for that State in the year named.

——Interesting statistical matter relating to Rhode Island is contained in the "Rhode Island Census for 1885," published by Mr. Amos Perry, Superintendent, and in the "Thirty-first Annual Report" of Dr. E. M. Snow, Registrar of the city of Providence.

——Dr. P. G. Unna, of Hamburg, forwards us a number of his separata, occupied with his researches into skin diseases and their therapeutics. He has given special attention to the uses of resorcin and ichthyol, and his observations merit the careful consideration of dermatologists.

——An article on the hygiene of old age, by Dr. H. C. Wood, has been reprinted in neat form. It is too brief to do the subject justice, and we hope the author will expand it into a monograph.

——The Boylston Prize Essay this year is upon a subject very important to the city physicians, to wit, the relation of hospitals to medical education. It is written by Charles F. Withington, and discusses the question with great clearness.

——Dr. Joseph Parrish, of Burlington, N. J., in his Presidential Address before the State Medical Society, attacks the prevalent notions of the cause of malaria, and advances some strong reasons for doubting the received theories on the etiology of that class of diseases.

——Dr. Beverly Robinson, of New York, in a reprint before us, denies that hay fever can be attributed to any one cause, or can be relieved by any one system of medication.

——The address of Dr. N. Senn before the American Medical Association, on the present status of abdominal surgery, has been reprinted in a neat pamphlet form.

——*La Vara de Esculapio* is the title of a journal which has been recently started at Barcelona, Spain. It is devoted exclusively to exposing infractions of the laws against the adulteration of foods, beverages, and medicines, and intends to speak without fear or favor. Such a project, if boldly carried out, cannot fail of exerting a salutary influence.

——A very sensible and suggestive article on the treatment of uterine flexions, by Dr. Virgil O. Hardon, of Atlanta, Ga., has been reprinted

——The statistics of several cases of enucleation with transplantation of eyes are contained in a recent pamphlet from the pen of Dr. Charles H. May, of New York.

——The School of Pharmacy of Purdue University, Lafayette, Indiana, sends its third annual announcement, and its bulletin, the latter containing a variety of original material.

——We should have noticed earlier Dr. Clara Marshall's address to the graduating class of the Woman's Medical College. It is a thoughtful and excellent oration.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

CHLORODYNE DRINKING.

At an inquest held recently in England on the body of a lady aged 62, of independent means, residing with two other maiden sisters, it was stated in the course of the medical evidence that all three of the sisters had been in the habit, for two or three years, of taking chlorodyne in large quantities, so much so that their bodies had become emaciated, their mental condition affected, and the use of their limbs had become impaired. The body of the deceased did not weigh more than fifty pounds, and death was due to continued overdosing of chlorodyne. The jury returned a verdict of death from continued overdoses of chlorodyne.

This case serves as a text for a few words of advice on the subject of the use of narcotics by the laity. Chlorodyne, chloral, morphia, bromide of potassium, cannabis indica, alcohol, and all similar articles, are, unquestionably, valuable drugs, but they are *drugs* all the same, and it is intended that they shall be used, not at the whim or caprice or demand of the laity, but upon the order of an intelligent and responsible physician.

The habit of using these drugs is regarded as a deteriorating one, a habit to be ashamed of, hence they are indulged in in secret, which, of course, makes it more or less difficult to accurately say to what extent such practices are carried, and how many persons are injured thereby; but the experience of nearly every one can recall at least one case wherein some relative or friend has become the victim of "the drugs that enslave," and where that which should have been a man or woman has become, through their agency, but little better than a beast. Is it not horrible for us to realize that our fellow-beings are so weak? but is it not painfully true that they are thus weak, and do we not feel that this terrible and growing evil appetite calls for recognition and opposition?

What shall we do? All over the country, we have now organized and growing in strength, a third political party whose battle-cry is the prohibition of the traffic in rum. Without entering into the merits of this party or principle, we would say that the prohibition of the indiscriminate traffic in narcotic drugs, is a question demanding the attention of the people as urgently as does the liquor question.

The future men of the country will be very much what their mothers, who carry them, make them. Comparatively few women are victims of the alcoholic habit, but a frightfully large number are addicted to the use of narcotic drugs. Is it reasonable

to hope that a chloral- or chlorodyne-saturated woman will be able to give birth to children worthy of being called human beings. We might as well look for gold in a dung-heap.

We require legislation, and most stringent legislation, on this point. It must be made a most grievous crime, punishable by the severest penalty, for a druggist to sell any of these drugs (and the forbidden articles should be specified) save on the prescription of a physician who is known to him to be a physician. How many of the feeble-minded and idiotic children, that cost the public thousands of dollars annually to maintain, are the logical results of these habits? God only *knows*, but man may feel sure that the number is very great. In the name of humanity, as well as for the interests of political economy, we emphatically say that this diabolical traffic must be restricted, and these would-be moral and physical suicides must be restrained of their morbid and damning propensities.

THE REMOTE EFFECTS OF REMEDIES.

This is a subject that is too seldom considered by the physician, hence we are pleased to see that attention was called to it at the recent meeting of the British Medical Association by Dr. Broadbent. The physician will do well not only to satisfy himself that he is giving the proper drug in a given case, but he will also do well to look beyond and consider what may be the remote possibilities of the drugs used. Thus, when a case of syphilis presents itself to the routine physician, he at once resorts to the use of mercury or iodide of potassium, whereas in many cases such drugs are not only not indicated, but are actually calculated to do harm. If a man very much broken down comes to us with syphilis, it is the part of wisdom to first "tone him up," as it were, before we resort to these specifics, for it is well known that these drugs have a remarkable tendency to weaken and debilitate those to whom they are given. So it is with many other drugs (malaria does not always call for quinine); for while the particular drug thought of may be capable of exercising a beneficial influence on the condition most obvious to the observer, there may be some reasons why the remote effects of it would be such as to more than offset the immediate benefits to be derived from its use.

In illustration of his remarks, Dr. Broadbent adduced the evil effects attending the habitual use of colchicum or of "specifics" by the gouty, or the misapplication of the "Banting" process by the obese, or the immoderate use of "Himrod" by the asthmatic; as well as the treatment, without regard to remote effects, of sick headache and of so-called indigestion. Other examples besides those noticed in detail—such as the injudicious use of purgatives—were necessarily passed over, but will readily suggest themselves.

He is the wise man who thoughtfully considers all these little points, for it is in such consideration, in such use of the brains with which we are endowed, that the superiority of one physician over another consists.

LEPROSY AND SYPHILIS.

In olden times when leprosy was rife the leper was an outcast. The civil law of the land compelled those thus afflicted to live apart from their fellows, and to cry out "*Unclean, unclean, unclean,*" whenever approached by one not of their kind. And why this seclusion? Because it was recognized that this horrible disease was contagious, and it was only by the strictest isolation that its spread was controlled. By such precautions the disease has been controlled, and it is only in certain portions of the world that we to-day hear of it. But, how about the syphilitic—is he not also *unclean*, and is it not dangerous to allow him to go abroad among his fellow men and women? What terrible havoc may be made by a man or woman with mucous patches in his or her mouth, and how many are so afflicted, unsuspected by their fellow men?

We full well know that sexual intercourse is not necessary for the transmission of syphilis from one to another; and so knowing, we ask whether there is not the same need to-day to isolate the syphilitic as there was in biblical days to prohibit the going abroad of the leper. If not, then why not?

NOTES AND COMMENTS.

Insane Delusions.

Before the St. Louis Medical Society, Dr. Bremer recently related cases of insanity, to illustrate the fact that the spirit of the times is generally reflected in the thoughts and actions of the insane. Many who would formerly answer imaginary voices at random, now use an imaginary telephone. The riots in East St. Louis had proved the exciting cause of insanity in two cases, and in both

existed the idea of being persecuted by strikers, though they had been quite unconnected personally with the riots. Another who became suddenly insane during an attack of acute rheumatic fever, had conceived and addressed a long letter to a daily paper setting forth his plans of meeting all difficulties with the strikers. Another, a skilful mechanic, invented a trap with which to ensnare Gould. In only one case had the doctor seen ancient events the groundwork of a delusion. This patient, a teacher of Greek and Latin, and a worker in mythology, imagined himself Jupiter and the universe, and he had given to each of numerous moles existing on his body the name of a star or planet.

Esmarch's Bandage in Anæsthesia.

We have already noted that Dr. M. J. Roberts has found that the use of a tight rubber band about a part will greatly prolong the anæsthetic effect of cocaine; and now we read in the *Bull. Gen. de Therap.* that M. Chandelux recommends the previous application of Esmarch's bandage when it is desired to produce local anæsthesia by means of the ether spray. He was led to make use of this procedure by the observations of M. Horand in 1867, who found that the difficulty of anæsthetizing a part bore a direct relation to its vascularity. The author claims the following advantages for his method:

1. Anæsthesia is produced in from twenty to forty seconds, while by the ordinary method two minutes or more are required.

2. After the spray is discontinued the anæsthesia remains for about three minutes, since the parts are not warmed by the blood-current.

3. The operation—for example, the removal of an in-growing nail—is greatly facilitated by the absence of hemorrhage.

The Prophylaxis of Puerperal Eclampsia.

Supposing that during pregnancy we find albumen present, we should give purgatives and keep the patient at rest and on a milk diet, says Dr. Jno. W. Byers in the *Dublin Jour. Med. Science.* Both Tarnier* and Chantreuil† recommend this form of milk diet. All nitrogenous food should be avoided, and a course of iron should be prescribed; if, however, the regular examination of the urine shows that the amount of albumen is large and *steadily* increasing, if there are casts and œdema of the face and upper extremities, and if, in addition, any cerebral symptoms appear, then undoubtedly labor should be induced without delay. Further, if towards the end of gestation the urine becomes diminished in amount, if there is a good deal of albumen, and if to these symptoms be added the presence of headache, we should at once administer chloral and keep a most careful watch on our patient, so as to be ready to induce labor if convulsions set in. We do not understand why we should give chloral, but we suppose Dr. B. knows what he is talking about. If we had a patient in this condition, we would resort to jaborandi for the drug treatment.

Cancer of the Mamma.

Prof. McCall Anderson, in the discussion on cancer before the Glasgow Pathological and Clinical Society, referred to the fact that cancer is more than twice as frequent in the female as in the male, which he attributes partly to the frequency with which the mamma and uterus are involved. He remarks that there is some difference of opinion as to whether it occurs more or less frequently in married or unmarried women. His personal observations have convinced him that it is much more frequent in the unmarried, and he suggests the following explanation. "The function of the breast is to secrete milk, and when the married woman has suckled her children, the gland passes into a state of quiescence or atrophy. To use a Disraelian expression, it may be regarded in the light of an extinct volcano. In the case of the unmarried woman, on the other hand, the breast is, so to speak, defrauded of its normal function, and as years go on, it is apt to fall into evil courses."

Whooping-Cough.

When the cough is convulsive, H. Roger (*L' Union Medicale*, No. 177) recommends the syrup of valerian in doses of 10 to 40 grammes, or tincture of musk in doses of 5 to 10 drops for children of two years old, and in doses of 10 to 20 drops for children about five years of age, and in doses of from 15 to 30 drops for children above five years old. On the occurrence of laryngeal spasm narcotic vapors from nitre paper of belladonna or stramonium are recommended. If the spasm is prolonged, chloroform or ether inhalations should be used. In extreme cases of spasm, inhalations of ammonia and sprinkling the face with cold water may be used; brisk hand-rubbing of the chest walls, especially over the heart, gives relief. Chlor-

*Le Progrès Médical. 1875.
†Leçons Cliniques. Chantreuil. 1881.

oform inhalations as a remedy for whooping-cough, were long since recommended in England by the late Dr. Fleetwood Churchill.

Poisoning from Sorrel.

A curious case of poisoning is reported in the *Hospital Gazette* of June 19, 1886, the chemical features of which possess especial interest from a medical jurist's point of view. The victim of the accident was a boy five years of age, who gathered and ate a quantity of sorrel growing in the vicinity of his father's house. Subsequently the symptoms to be expected from the action of the poison contained in the leaves set in, and, to quench the thirst from which he suffered, the little fellow swallowed a quantity of soapy water which chanced to be within his reach. Death speedily ensued, and, post-mortem, the stomach was found to contain oxalic acid in considerable amount. The action of the alkali in the soap swallowed had resulted in the production of soluble oxalate, by absorption of which the fatal event had been precipitated.

The Treatment of Goitre.

As a rule, the treatment of this disfiguring affection is not satisfactory. Hence, though our experience may not bear it out, yet it will be well to try the hypodermic injection of carbolic acid, as recommended by Dr. O. E. Haven, in the *Weekly Medical Review.* He injects from 20 to 35 minims of a five per cent. solution once or twice a week, inserting the needle from half to one inch into the gland. Out of the 150 or 200 cases treated in this manner, there were only two cases where any inflammation and feverish symptoms appeared, and in these cases they only lasted a day or two. The treatment is said to be simple, almost entirely painless (as the smallest needle of the hypodermic syringe can be used, and is entirely effective). No other treatment can show such uniformly successful results.

Permanganate of Potash in Carbuncle.

Dr. Fenn, of California, believes that anthrax may be materially abridged in duration, if not aborted, by the use of this remedy. As soon as the vesicles give way, exposing the characteristic cribriform openings, gently express a portion of the contents of the tumor and replace with a strong solution of potassium permanganate. This may be introduced twice a day with a grooved director or hypodermic syringe. It is understood, of course, that this salt is readily decomposed by contact with organic matter, but meanwhile something has been done to diminish the tendency to sepsis and toward "resolving the inflammation." As carbuncle is not merely a local lesion, the systemic condition of the patient should be attended to, and pain mitigated.

Gastric Ulcer.

Beyond rest and milk diet, our teachers seldom give us much advice about the treatment of this not uncommon complaint. That we ought to do more, we all feel; but what? Dr. C. S. Blount reports a case in the *Cinn. Med. Jour.*, wherein acetate of lead and morphia controlled the hemorrhage. The pain was allayed by subnitrate of bismuth and sulphate of morphia. Belladonna plasters over the seat of pain gave relief. Bicarbonate of soda with subnitrate of bismuth immediately relieved the burning distress in the stomach. After commencing to take cod-liver oil and glycerine, flavored with cinnamon, the patient ceased to vomit. The patient very much improved, though still having a heavy feeling and pain in the stomach.

The Diagnosis of Gonorrhœa in Females.

At a recent meeting of the *Société d Obstétrique et de Gynécologie*, of Paris, Dr. Martineau brought an important fact to the knowledge of the society, by means of which the discharge of gonorrhœa in the female can be distinguished from simple vaginal discharge. In the specific form, he says, the discharge is always acid, while in the simple form it is always alkaline. If this really be the case, it is very easy to decide with a bit of litmus paper whether the woman is, or is not, suffering from gonorrhœa. This sign may also prove of value in cases of rape, in deciding whether the person who committed the crime was suffering from gonorrhœa at the time, as any vaginal discharge from this cause would be acid.

Anæsthesia During Sleep.

There has been much discussion as to whether it would be possible to etherize a man during sleep. We doubt it. Dr. John S. Marshall writes to *The Lancet* that he succeeded in producing anæsthesia in a sleeping man by the A. C. E. mixture. The patient was a strong collier, who was brought to the infirmary with a fractured thigh. Being worn out with pain, he fell asleep before

his leg could be dressed. Dr. Marshall found him asleep, induced anæsthesia, and bandaged the thigh, without awakening him. The question arises whether this man's condition could be called that of *true sleep;* was he not rather in a condition of *stupor?* We are not told whether he was *alcoholized* or not.

Poisoning with Castor Oil Seed.

At Ipswich, in Queensland, two children were lately poisoned by eating some castor oil seeds. Fortunately the prompt use of emetics saved their lives. It is not sufficiently known that the seeds of *ricinus communis* are poisonous, though the fixed oil is perfectly safe to use. We remember that a member of the "Nyanza expedition" to Central Africa, finding an indigenous castor oil plant growing there, partook of eight seeds, thinking that number would yield about the average dose of oil; but the missionary nearly lost his life by the imprudent experiment, and learned a wholesome lesson from the painful experience.

Tinea Versicolor—Its Resemblance to a Syphiloderm.

The *Kansas City Medical Index* says that a very practical illustration was given the other day of the striking resemblance between this affection and a syphiloderm. The patient contracted syphilis several months since, was treated for a while, and disappeared. Three weeks ago he presented himself again, and was much excited over a brownish eruption that covered his breast. Of course it was what would be expected, and after a casual examination he was prescribed for. Returning two weeks later with a marked improvement in his general condition, the eruption remained the same. A close examination showed that the eruption bore no relation to the syphilis, but was tinea versicolor.

Progressive Pernicious Anæmia.

He is truly a valuable contributor to medical science who makes known the *complete* as well as the partial results of his cases. A few cases of complete recovery from this disease have been reported; but it is worthy of note that these cases were hospital patients, and that as soon as they had regained a fair degree of health they were discharged as cured, and most likely lost sight of.

Last November, Dr. I. A. Loveland, of Gilsum, New Hampshire. reported a case wherein an apparent cure had been effected; but to his credit be it said, he is honest enough to come out in the *Med. Times* (Sept. 4) and tell us that a couple of months later his patient had a relapse and died. Were all men equally honest, it would be a good thing.

Ergot in Parturition.

An uncontracted uterus will, of course, offer many gaping sinuses, all avenues for the entrance of disease germs to the body. Therefore Dr. V. M. Richard speaks wisely when he recommends (*Med. Times*, September 4,) that we should give ergot after the expulsion of the placenta. It should not be given until the placenta is under entire control; then should be given several doses in quick succession until the womb is well contracted and low down; and after this a drachm every four hours. The rapidly repeated doses may cause vomiting, but he has never seen any bad results follow this. On the other hand, the womb seems to contract more forcibly.

The Treatment of Typhoid Fever.

The hope of cutting short the usual course of the specific fevers still lingers in the mind of practical physicians, though it must be confessed that there does not appear to be much encouragement in store. M. Pecholier, of Montpellier, is of opinion that he had discovered the means of causing the premature termination of ordinary cases of typhoid fever. The agent is the familiar quinine, administered in daily doses of not less than one gramme, and this from the very first days of the illness. The drug may be aided by the employment of tepid baths if there be considerable fever, and by small doses of digitalis should the heart be specially disordered.

Poisoning by Sulphuric Ether.

Such cases do not very often present themselves, but when they do it is well for you to know how to relieve them. Therefore we note from the *Kansas City Medical Index* that Mrs. G. had taken with suicidal intention a half-ounce of sulphuric ether. Dr. L. A. Wohlfarth saw her one hour after she had taken the ether. Symptoms: cold hands and feet, pulse and heart's action very feeble, respiration about eight per minute, considerable cyanosis, cold perspiration on forehead and face, unconscious. Treatment: Injected subcutaneously, by repeated injections, about one ounce of whisky. Recovered.

Salicylate of Iron for Diarrhœa.

The use of a mixture containing salicylate of iron is recommended by Braithwaite, of Leeds, in cases of diarrhœa in children where the motions are fetid. The formula for a child two years of age is—Sulphate of iron. ℈j; salicylate of soda, ℈j; glycerine, ʒiij; water to three ounces. The iron and the salicylate should be dissolved separately, and the solutions mixed; the color is darker than port wine, and the taste is said not to be unpleasant. One teaspoonful to be given every hour until the motions become well blackened, and then at longer intervals, with an occasional dose of castor oil to counteract the constipating effect.

Ethyl Bromide.

In the *N. Y. Med. Jour.*, Dr. E. K. Shurley tells us that he has used this article almost entirely as an inhalation for the relief of cough. He has tried it in a large number of cases; it is not qnite so efficacious as as chloroform, but there is much less general anæsthesia from its continued use, and it leaves no unpleasant after-effects. He thinks, therefore, that it is deserving of more extended use for the relief of severe dry cough and spasmodic asthma.

Drops for Earache.

Pavesi recommends a mixture of camphor chloral 2½ parts, glycerine 16½ parts, and oil of almonds 10 parts. This is to be well mixed and kept in a well-closed bottle. A pledget of absorbent cotton is to be soaked with the drops, and then introduced as far as possible into the affected ear, two applications being made daily. Frictions may also be made each day with the preparation behind the ear. The pain is almost immediately relieved.

The Diagnosis of Alcoholic Paraplegia.

As an alcoholic will rarely admit his habit, it is well to have some signs by which it may be discovered. Dr. Robert Saundby (*Lancet*, Aug. 7), draws special attention to the diagnostic significance of the painfulness of hyperæsthesia of the muscular masses. He does not assert that this symptom is absolute proof of alcoholism, but it is of the highest value in directing your suspicions in that direction.

Labor Followed by Suppression of Urine.

In the *Lancet*, Aug. 7, Dr. J. T. Williams reports the case of a woman who, for five days after a normal labor, had passed only two ounces of urine, when she died. No post-mortem was allowed, which leaves the case in an unsatisfactory condition, though, no doubt, it was one of those nasty, insidious, unsuspected, and suddenly fatal cases of Bright's disease, that one occasionally meets.

Paraldehyde.

Paraldehyde is so unpleasant to the taste that the following formula, which is Elvy's, and is adopted by Spanish physicians, and is said to form an agreeable mixture, will be acceptable:

℞.	Paraldehyde,	1 to 4 grammes.
	Distilled water,	70 grammes.
	Simple syrup,	30 grammes.
	Tincturæ vanillæ,	25 drops.

Half for a dose.

Warts on the Genitals.

The *St. Louis Med. and Surg. Jour.* says that acuminated warts are often observed upon the genitalia, more often in the sulcus right behind the glans penis in the male. Whilst they are harmless, from a cosmetic point of view they are best removed; and to do this effectually, one of the best methods is to apply chromic acid to them, or snip them off with scissors and apply the acid to the base.

Ointment for Inflammation of Veins.

We take the following from the *Jour. de Med.:*

℞. Purified lard, 30 grammes.
Extract of opium.
" " belladonna.
" " hyoscyamus.
" " hemlock.

Sing.—3 grammes.

To be made into an ointment, and applied over the inflamed veins daily.

Cancer Powder.

The following powder is said to kill the fœtor of cancerous ulcers, and to stop the pain:

℞.	Iodoform,	18 grammes.
	Quiniæ sulph.,	3 "
	Essence of mint,	40 drops.
	Charcoal,	15 grammes.

To be dusted over the ulcer daily.

Sozolic Acid.

This substance, called also orthoxy-phenyl-sulphurous acid, is said to possess superior antiseptic properties. It has been used internally as well as externally in erysipelas, small-pox, pneumonia, phthisis, and other

affections, with, it is claimed, excellent results.

Mixture for the Inappetence of Pregnant Women.

Forwood recommends the following:

℞. Pulv. colombo rad.,
Pulv. zingiber rad., āā 15. = ℥ss.
Fol. sennæ, 4. = ℥j.
Aquæ bullientis, 475. = Oj.
Ft. infusio. Sig.—A wineglassful before each meal.

Platt's Chlorides.

As a disinfectant and antiseptic, we have found these chlorides render excellent service during the summer and autumn. They can be employed in town and country with equal advantage, and will prevent the risks arising from neglected sewers, wells, etc.

Cobden's Fluid Extract of Beef.

This preparation has long held an established position as a concentrated animal food and dietetic stimulant. It has every guarantee of careful preparation and uniform quality.

News and Miscellany.

Chevreul's Household.

The household of this celebrated French chemist, whose centennial birthday was celebrated on the 31st of August, is thus described by the *Chemist and Druggist:*

"His residence is a large, comfortable-looking, but very old-fashioned mansion, the court of which opens on one side of the Gardens, and on the other on the Rue Cuvier. Chevreul is a widower, his wife having died in 1862, and he has a son now seventy years old. His household consists of Denise, the housekeeper; Isoline, the cook, and a coachman. Denise is quite a character. She has been forty years in Chevreul's service, and is not a little proud of her master's old age, which, she thinks, is to a great degree due to her constant care and attention. She is not, perhaps, wrong there altogether. Her only pre-occupation is to minister to his wants, to forestall all his wishes and fancies. As he hates to be disturbed by strangers, she stands watch and guard over his privacy, and will not allow a reporter within earshot. During his late sickness she would coax him like a child to make him take his medicine. For her and Isoline the whole world is contained within the precincts of the Jardin des Plantes, and their master the only being of consequence therein. In thirty years they only went six times to the theatre. Isoline, the cook, has the ways and deportment of a true *cordon-bleu,* who appreciates the dignity of her office and means to live up to its requirements. Her master's tastes are very simple, but she will have everything of the best for him. She simply worships him; she can enumerate all his chief discoveries, and then she will add, 'But he is so disinterested, he never tried to make any money out of his inventions, else he would be to-day a hundred times a millionaire!' And, indeed, Isoline is not very far wrong in her appreciation. She has been twenty years a member of Chevreul's household.

"The coachman is comparatively a new comer, as he has been only fifteen years in the house. His sole care is to mind the old horse and to drive his master to the Academy of Sciences, the Agricultural Society, and the Gobelins on stated days, at a precise hour and by a route that must never vary. Only lately a short drive in the Bois de Boulogne has been indulged in after the scientific meetings. When the old steed is disabled Chevreul takes a hired coach, but his coachman insists upon driving himself or sitting by the side of the driver. As a visitor was one day complimenting the two women on the length of time they had remained in the same service—a rare thing nowadays—one of them replied, 'Well, sir, you see, good masters make good servants.'"

Patent Medicines in America.

The *Western Druggist* informs us that recently published statistics state there are 5,000 proprietary articles of home manufacture on the American market; 500 of these are of commercial importance, and 50 are run as an independent business. The patent medicine trade of the United States is $22,000,000 annually; of this $10,000,000 is annually expended in advertisements, and the net profit amounts to $5,000,000.

The traffic is the work of the past half century, most of the patent medicines having sprung up since 1830. Not one in a thousand patent medicine men has succeeded. There are five firms which have made $1,000,000 each; twenty others will aggregate $5,000,000, and the net savings of all the rest will not reach another $5,000,000. More patent medicines proportionately are sold in the United States than elsewhere. The great middle class buys most of them.

The profits from and expenditures on established patent medicines run about as follows:

Expenses.	Per cent.
Cost of material, labor, and expense	24
Advertising	12½
Jobbers' expenses	03½
Retailers' expenses	21
Total expenses	61
Profits.	
Manufacturers' profit	12½
Jobbers' profit	05½
Retailers' profit	21
Total profits	39

The smaller country newspapers subsist largely upon advertisements of these "remedies," and at least $100,000,000 have been paid newspapers during the last two decades, while upward of $5,000,000 have been expended in rock and fence advertisements.

The field for new patent medicines is narrowed every day. Cathartic pills and sarsaparillas do not succeed readily, because so many well established specimens occupy the field. Until the stamp tax was abolished, patent medicines yielded the government $1,800,000 annually. The census of 1880 shows that there were then 563 establishments in this line in the United States, employing 4,015 operatives; that the capital invested was $10,620,000, and that the value of the annual outfit was $14,682,000. New York stood first in the amount of capital invested ($3,512,430), and in annual output (nearly $4,500,000); Pennsylvania second in capital invested, $2,000,000, and third in annual output, $1,000,000; Missouri third in capital, $1,500,000, and fourth in annual output, $750,000; Ohio fourth in capital, $570,000, and fifth in annual output, $450,000; Massachusetts fifth in capital, $521,000, and second in annual output, $1,500,000.

Suicide in Russia.

Some instructive statistics are published by a St. Petersburg paper (the *Novosti*) with regard to the concurrent increase of suicide and insanity in Russia. The inmates of the asylums at St. Petersburg have doubled within the last ten years, and this is ascribed by the *Novosti* to the great spread of pessimistic and Nihilist doctrines. In the early part of the century the number of suicides was at the rate of only 17 per 1,000,000 inhabitants, while it is now nearly 30 per 1,000,000, and in St. Petersburg itself there are more suicides than in any other capital of Europe, except Paris, there being 206, as against 170 in Berlin, and 87 in London. The increase commenced about twenty-five years ago, and of late years it has been so rapid that while the population has risen by only eight per cent., the increase in the proportion of suicides has been 76 per cent. The number of cases of insanity has not kept pace with the number of suicides, though they, too, have increased at the rate of 35 per cent.; and it is pointed out that, while meat is 20 per cent., and house rent 35 per cent. dearer than it was, the number of suicides has been out of all proportion greater, so that want cannot be the sole cause of this increase. The most distressing part of this return is that which tells how no fewer than 42 boys and 15 girls between eight and sixteen years of age committed, or attempted to commit suicide in the last ten years, mostly because their parents maltreated them.

Medical Inspection in Brooklyn.

The Brooklyn Commissioner of Health, Dr. Andrew Otterson, has inaugurated in that city an admirable system of medical inspection and relief in the tenement-house districts, with special reference to the diseases of infants during the heated season. Ten physicians have been appointed, each assigned to a special locality, who are instructed to search for sick children needing attention, and to care for them, furnishing medicine gratuitously where parents are unable to pay for it, and at a reduced price to those who can. They are to note the condition of premises and report where sanitary improvements are needed, give advice as to healthful manner of living, urge parents to take their children into the fresh air as much as possible, and give orders on the diet dispensaries for proper food when it cannot be obtained otherwise. The salaries of the physicians ($75 a month) are to be paid out of the emergency fund. As a contrast to this beneficent movement in Brooklyn, the New York Board of Appointment this year refused to allow the appropriation devoted last year to similar uses, with the result of a marked increase in infant mortality in the crowded districts of the city.

Why Some Young Doctors go to Europe.

The Vienna correspondent of the *Weekly Medical Review* says:

"I asked a new graduate of one of our Western schools, where I know clinical advantages are at a minimum, to go with me to hear Bamberger. His first question to me was, "Doctor, what is your specialty?" My

reply was internal medicine in its broadest sense, with all the gynecology I can find to mix in. His reply was, "Doctor, you make a great mistake; take some specialty—that is all the rage in America! I am after the throat, and when I get back to Indiana I shall expect to do a big business." What absurdity, when we consider the vast and intimate relation of the diseases of the throat and nose to other organs of the body, for a young man to take up such a specialty before he is a thorough physician in the widest acceptation of that term! He further told me he did not understand German, and had no idea of attempting to learn it; that he had spent some time in New York in a throat clinic, and he believed that the advantages there were far superior to what could be gotten in Vienna, but that a man must have the reputation of having studied in Vienna, or it was no go in a large town in America."

The Men who Want Offices.

The *St. Louis Med. Jour.* says that the attitude of some men toward office is that of the historical old maid toward matrimony. She had been in this vale of sorrows a long time, and was getting mighty weary of watching and waiting for a husband. She could not sew, nor bake bread, nor clean up a house—at least nobody ever saw her doing anything of this sort—but she was very eloquent, and one day she concluded to try her eloquence on the Lord. She went down into the wilderness, and kneeling under a tree, prayed long and fervently for a husband. While she was sending up a silver-tongued appeal to the throne of grace, an owl overhead screeched out *who-who-oo*. Thinking that her prayers were about being answered, she exclaimed joyously: "Anybody, good Lord! Anybody, so it's a man." Anything, good people! anything—so it's an office. If I can't be Coroner, give me the City Hospital; and if I can't have *that*, give me the Lunatic Asylum.

The Prevalence of Infanticide in China.

Is it not singular how radically different in certain peculiarities are different races of man. To the American who dotes on his children, it is almost inconceivable that the lives of these little ones should be held so lightly by his Oriental brethren; for from the *Med. Record* we learn that there is a missionary society in existence, with its headquarters in France, the object of which is the rescue of Chinese infants abandoned to die by their parents. Colonel Cheng-Ki-Tong, in a recent work, "Les Chinois Peints par Eux-mêmes," denied that such a custom prevailed, and held up to ridicule the children belonging to this society, who, he said, were beguiled into giving their pennies for the rescue of infants who did not need rescue. Dr. D. J. Macgowan, however, in a paper in the *China Review*, shows that this custom is prevalent in many parts of that country, to such an extent, indeed, that numerous asylums have been erected by charitable individuals among the Chinese themselves for the reception and care of these neglected infants. Female children are the only ones drowned, boys being needed to conduct ancestral worship. The parents are usually very willing for a little cash to sell their girls, instead of destroying them.

The Man with Fetid Feet.

The *Cinn. Lancet-Clinic* asks, what woman is there who enjoys a tobacco smoker's breath, or a husband with *bromidrosis* or fetid feet? Yet Louis XIV., according to Fragon, suffered from the latter to such a degree that the worst courtesans in Paris fainted away at the first whiff of his perfumed feet.

Henry IV. had the same redolent perfume, but this did not prevent the diplomatic Queen Marguerite from occupying the same couch; and she pardoned her liege lord's legendary infidelities, as well as the loud smell of his royal toes. One day he was so redolent that Madame de Verneuil, one of his court favorites, said to him: "Sire, it is fortunate you are king; without that your presence would not be tolerated—you stink worse than carrion."

A woman may passionately love a hump-back, a cripple, a legless or an armless man, but she can never love a man with a bad breath, or smelly feet, and we may remark *en passant* that the *German army have hereditary bromidrosis*, and its soldiers are obliged by law to use a deodorant powder of salicylic acid on their odorous, tyrannical feet.

"A Boy with Cat's Eyes."

A case with this heading is reported as now exciting the attention of the oculists of Chicago. Mrs. Quinn, of 471 Wells street, recently visited the State Eye and Ear Infirmary in company with her son, who possesses the peculiar power of seeing in the dark. One of the surgeons, Dr. Charles F. Sinclair, called in several other oculists to examine the anomaly. The boy was taken into a dark room, and various tests were applied. The eyeballs glistened like balls of

fire. The larger portion of the iris is missing, only a small portion being visible on the outer side of each eye. When taken into a dark room an immediate expansion takes place, which enables the boy to see perfectly. A strong light blinds him, and from this same peculiarity the boy is able to see objects at a distance with much more clearness than those close at hand. It seems to be a case of coloboma of the iris and choroid, with defective development of pigment, and perhaps with a hyper-sensitive retina.

Reindeer Milk.

The *National Druggist* tells us that the exceeding richness of the milk of the reindeer which feeds upon the moss of northern Asia has repeatedly excited the wondering comment of explorers and travelers, and has recently led to a chemical examination and analysis of the moss itself. The *Paint, Oil, and Drug Review* says that the investigation has disclosed the fact that the substance is extremely rich in alcohol, yielding as large a percentage of that commodity as grain. It is said that the alcohol is readily produced, and that the deposits of moss are practically inexhaustible, covering a wide belt of territory, and extending from the Ural Mountains to Behring's Straits. Only the difficulties and expense attendant upon transportation prevent the working of so rich a source of wealth, and it is possible that the genius of speculation may be able to devise means by which these may be surmounted.

Don Quixote from a Medical Point of View.

Dr. Don Emilio Pi y Molist, who is described as the "doyen" of Spanish alienists, has recently published a work, entitled "The Beauties of Dan Quixote from a Medico-psychological Point of View, with General Remarks on Madness and a New Commentary on the Immortal Novel," with which the profession in Spain are greatly delighted, and a grand banquet has just been given to Dr. Pi in Barcelona, as a mark of the appreciation of his professional brethren of the work referred to. As "the immortal novel" is read by thousands of foreigners, it is to be hoped that some one will have the goodness to translate Dr. Pi's new work into some language more universally read than Spanish.

A Hairy Child.

There is being exhibited at present in Paris a type of a very primitive race of humanity. It is a very curious specimen, entirely covered with hair, the skin very dark; the child would remind one of the chimpanzee. The hairs on the arms and legs follow the same direction as those on the monkey; the legs are thin and short, while the arms are very long. It appears that the tribe to which she belongs dwell more on trees than on the ground. The child is twelve, and seems to have a certain intelligence, and takes great interest in her doll. Her eyes and hair are very fine, her nose is flattened, and her ears are deprived of cartilage. She has thirteen pairs of ribs, and consequently thirteen dorsal vertebræ. The race to which she belongs is found in the north of Siam, and several families are kept at the court of the King of Siam.

Dangers of Self-dosing.

Another instance of the dangers attending the unguarded use by persons suffering from extreme pain of medicines which, taken in large and unprescribed quantities, are productive of poisoning and death, is illustrated by the circumstances surrounding the death of a woman aged 52, who, it appears, had been in the habit of taking laudanum for neuralgia. Recently her husband returning home, found her sitting in a chair apparently asleep. He left her there and went to bed. On awaking the next morning, he found her in the same position in which he had left her the previous evening, and insensible. He noticed that a bottle that had contained laudanum was empty. Medical aid was called in, and she was removed to the hospital, where she died three hours after admission.

Sanitary Convention in Michigan.

A sanitary convention is announced to be held at Big Rapids, Michigan, under the auspices of the State Board of Health, on Thursday and Friday, November 18th and 19th. Discussions are expected to be held on the following subjects: "The Sewerage and Drainage of Big Rapids," "The Water Supply of Big Rapids," "The Hygiene of Schools, with special reference to Big Rapids," "Pasteur and Protective Medicine," "Public Health Laws," "The Sanitary Needs of the City of Big Rapids," "Alcoholic Drinks—are they Foods or are they Poisons?" "The Injuries of Every-day Drug-taking," "What to Eat, When, and How," "The Care of the Eyes," and "The Prevention of the Communicable Diseases."

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE THREE WEEKS ENDED SEPTEMBER 4, 1886.

Bailhache, P. H., surgeon. To proceed to Cape Charles Quarantine as inspector, August 27, 1886.

Fessenden, C. S. D., surgeon. Granted leave of absence for thirty days, August 30, 1886.

Godfrey, John, surgeon. To proceed to Biloxi, Miss., and investigate alleged yellow fever cases, September 1, 1886.

Irwin, Fairfax, passed assistant surgeon. Granted leave of absence for thirty days, September 2, 1886.

The Czar's Contribution to the Pasteur Fund.

Newspapers hostile to Pasteur have lately been circulating reports asserting the deaths of several of the Russian patients formerly treated in Paris. Owing to the remoteness of the places where the alleged events occurred, it has been very difficult to ascertain whether the information is correct or not. But the Emperor of Russia, who ought to be a good judge of the facts, appears to be so well satisfied with the results of Pasteur's treatment that he has just sent a munificent donation of 40,000 roubles ($20,000) towards the erection of the proposed hospital in Paris. With this new addition the hospital fund now amounts to 1,600,000 f. ($320,000), a sum sufficient to erect quite a snug building.

Origin of Alcohol.

According to the Talmud, one theory concerning the origin of alcohol is as follows, viz.: Noah planted the first vineyard, Satan being present and assisting in the work. After the vineyard was planted Satan slew a lamb, a lion, an ape, and a hog, and with their mingled blood watered the roots of the vines. This he did, he said, because he who shall taste for the first time of the juice of the grape will be a lamb; he who shall use it in moderation will become—for the time being—a lion; he who shall use it to excess will become an ape, and he whom it shall master will become a hog.

All for the Love of a Woman.

A prominent wholesale house of St. Louis recently received the following self-explanatory letter:

——, Ark., June 14, 1886.—Mr. ——: *Dear Sir:* I will asked you to Sent me ten Cts worth of love Powders this for to Gain the love of a good girl or tell me how to gain the love of a girl or tell me Some good way for to gain the love of a girl As the old Saiing a Fool for luck so hear i try you for infirmachien give me a trile Beshuar and send me some love powders and also tell me how for to yoused them and tell me if thar is aney thing that a man Can make a girl love a man Remain as yours Truly Respectful

---

A Peculiar Form of Dropsy.

Dr. M. Pargamin writes, in the *Russkaya Meditsina* of April 27, 1886, that he was called to see a young woman who was said to have dropsy, which the brother thought she had caught from one of his fellow-workmen who was suffering from a similar affection. On examination, it was found that the woman was in labor, the child presenting by the arm. Dr. Pargamin turned and delivered, but the abdomen was still much distended, and it was not until two more infants appeared that the dropsy was definitely cured.

The Great Washington Doctors.

The *Medical Age* tells us that a member of Congress from the West received the following from one of his constituents:

"*Dear Sir:* My children have been afflicted with scabs all winter, and the medicine given them by the doctor here does not seem to do them any good. I see by the papers that there are some very fine doctors in Washington connected with the government, and if it does not cost too much, I wish you would ask them what is good for the scabs, and write me by return mail."

Adulterated Poison.

A press dispatch says: "There is some good in adulteration after all," is the opinion likely to be held by a Pennsylvania man who lately attempted suicide with Paris green, for the physician who was called to him is reported to have said that he could not have saved him if the poison had not been adulterated.

Chlorphyl Under Water.

An interesting discovery has been made in Switzerland of a bright green moss, growing on calcareous rock, 200 feet below the sur-

face of Lake Leman. No other moss has been known so far under water, and how chlorphyl—the green coloring matter—could have been so richly developed in a place so remote from the light, is a problem—probably the extraordinary clearness of the water enabling the sun's rays to penetrate to a great depth.

The Bicycle and Prostatic Disease.

The *California Practioner* says that horsemen, after the age of forty, begin to exhibit evidences of disease of the prostate gland. This being true, it is evident that the rider of the bicycle is much more likely to acquire such disease. The genito-urinary specialist will rejoice in the prospective harvest afforded by the increasing use of the bicycle.

Death of Chicago's First Druggist.

Philo Carpenter, who, it is said, was the first person to open a drug-store in Chicago, died August 5. Mr. Carpenter was born in Savoy, Mass., in 1805, and went into business in Chicago about 1830, becoming a wealthy and highly-honored citizen.

Pasteur's Work.

Professor Virchow is reported to have said, in a recent lecture in Berlin, that Pasteur had done the world a great service if he had succeeded only in allaying the fear consequent upon the bite of a mad dog.

Items.

—Hydrophobia does not exist in Lapland; but two dogs brought from that country having been inoculated by M. Pasteur, contracted rabies, proving that Lapland dogs are not refractory to the disease.

—It is reported that another of M. Pasteur's patients has just died at Leste, near Bordeaux, after undergoing ten inoculations. The victim is a little boy named Cladicie, aged 3½ years, who was bitten by a mad dog on June 14 last.

—An Irishman was summoned for refusing to pay a doctor's bill. He was asked why he refused to pay, "What for should I pay?" said Mike; "shure he didn't give me anything but some emetics, and divil a wan could I kape in my stomach at all, at all!"

—"Allopathy" was a term coined by Hahnemann to indicate the converse of homœopathy, from the Greek *allos*, other, and *pathein*, to suffer. It is defined in the Sydenham Society's Lexicon as "the curing of a diseased action by the inducing of another of a different kind, yet not necessarily diseased."

—A botanist has estimated the number of seeds in some of the common weeds of the United States, as follows: Shepherd's purse, 37,500 per plant; dandelion, 12,108; wild pepper grass, 18,400; wheat thief, 7,000; common thistle, 65,366; camomile, 15,920; butter weed, 8,587; rag weed, 4,366; common purslane, 388,800; common plantain, 42,200; burdock, 38,068.

—The annual meeting of the German Ophthalmological Society was held in Heidelberg on August 9. It was attended by one hundred and fifty visitors from all parts of Europe. The von Gräfe gold medal for the most valuable contributions to ophthalmology during the last ten years, was presented to Professor von Helmholtz, of Berlin.

—On the authorities making an examination of the wells of Nakamachi (Japan) recently, 777 out of 939 were found to be unfit for drinking purposes, and the analysis of many showed traces of sewage contamination. Such a condition of the water-supply leaves room for no surprise at the statement that cholera has taken root in many places in the country.

—Some works in the National Library of Pekin contain undeniable proof that Chinese medical men, at an early period, used anæsthetics during their operations. This practice is due to a celebrated Chinese physician who lived at an epoch between the 220th and 230th year of the Christian era. They administered to their patients hachish (cannabis indica), which rendered them insensible.

—Dr. Ireland's book, "The Blot upon the Brain," is to be translated into German. The French translation of this book, which is being prepared by Dr. Edgar Betillon, of Paris, is nearly finished. The "Blot" has been prohibited by the Russian Censorship. This is, no doubt, owing to the chapter on the hereditary insanity of the Romanoffs, and the historical illustrations about the harm insane monarchs have caused to their subjects.

DEATH.

WILLS.—July 10, 1886, at his residence in Earleville, Cecil county, Md., Dr. Samuel E. Wills, in the 63d year of his age.

Pallas Syringe." The most useful Instrument for Vaginal Medication and Irrigation.
